# **PROJECTIVE-UMBILIC POINTS OF CIRCULAR REAL HYPERSURFACES IN**  $\mathbb{C}^2$

DAVID E. BARRETT AND DUSTY E. GRUNDMEIER

ABSTRACT. We show that the boundary of any bounded strongly pseudoconvex complete circular domain in  $\mathbb{C}^2$  must contain points that are exceptionally tangent to a projective image of the unit sphere.

### 1. BACKGROUND

<span id="page-0-0"></span>A *vertex* of a smooth plane curve may be viewed as a point at which there is a circle exceptionally tangent to to the curve; that is, there is a circle with fourth-order (or better) contact with the curve at the vertex in contrast with with the situation of a non-vertex at which third-order contact is the best possible. (What we are calling the order of contact here is also known as the "point-contact order" [Rut,§5.1.1]. An alternate convention – used for example in the study of jets of functions – reduces the orders by one.)

The famous four-vertex theorem ([Muk], [Kne], [Oss]) says the every smooth Jordan curve in the plane has at least four vertices. There are corresponding results giving lower bounds for the size of the set of *affine vertices* where a curve is exceptionally tangent to a conic [Muk], for the set of *umbilic points* on a smooth non-toric compact surface in  $\mathbb{R}^3$  where the surface is exceptionally tangent to a ball (see for example [Ber, pp. 389-390], noting the unresolved Carathéodory conjecture), for the set of points where an orientation-preserving diffeomorphism of the unit circle is exceptionally tangent to a holomorphic automorphism of the unit disk ([Ghy], [OvTa]), and for the set of *CR-umbilic points* on the boundary of a real ellipsoid or bounded complete circular domain in  $\mathbb{C}^2$ that are exceptionally tangent to a local biholomorphic image of the unit sphere ([HuJi], [EbSo]; note also the counter-example in [ESZ]). (The order of contact at stake in the last batch of results is seven, and the points in question are those where a certain sixth-order tensor (due to Cartan [Car1], [Car2]) vanishes.)

In the current work we again consider real hypersurfaces in  $\mathbb{C}^2$  or the projective space  $\mathbb{CP}^2$ , looking at orders of contact with projective images of the unit sphere (equivalently, with ℂ-affine images of the unit sphere or the Heisenberg hypersurface  $\{\text{Im } z_2 = |z_1|^2\}$ . The special points are the *projective-umbilic points* at which third-order contact is possible.

Due to the discrepancy in the collection of allowable maps on the one hand and the order of contact on the other hand, CR-umbilic points need not be projective-umbilic, nor vice versa (see Example [6](#page-2-0) below.)

We show below that boundary of any bounded strongly pseudoconvex circular domain in  $\mathbb{C}^2$ must contain projective-umbilic points.

## <span id="page-1-2"></span>2. A BELTRAMI-STYLE TENSOR

The following tensorial object will prove useful: for *S* a smooth real strongly pseudoconvex hypersurface in  $\mathbb{C}^2$  with defining function  $r$  we set

(2.1) 
$$
\mathscr{B}_{S} \stackrel{\text{def}}{=} -\frac{\det \begin{pmatrix} 0 & r_{1} & r_{2} \\ r_{1} & r_{11} & r_{21} \\ r_{2} & r_{12} & r_{22} \end{pmatrix}}{\det \begin{pmatrix} 0 & r_{1} & r_{2} \\ r_{1} & r_{11} & r_{21} \\ r_{1} & r_{11} & r_{21} \\ r_{2} & r_{12} & r_{22} \end{pmatrix}} \cdot \frac{dz_{1} \wedge dz_{2}}{d\overline{z_{1}} \wedge d\overline{z_{2}}}
$$

on *S*, where the subscripts denote differentiation. (The non-vanishing of the denominator here is well-known to be equivalent to the strong pseudoconvexity of *S*. The last factor above is to indicate that this object is to be viewed as a section of the product of the canonical bundle of (2*,* 0)-forms with the conjugate-inverse of that bundle. We will refer to such objects as Beltrami differentials. (In a one-variable setting this reduces to the reciprocal of the Beltrami differentials  $\mu(z) \frac{d\overline{z}}{dz}$  $\frac{dz}{dz}$  used in particular in the study of quasi-conformal mappings, as for example found in [Leh]. See also [§5](#page-4-0) below.)

<span id="page-1-1"></span><span id="page-1-0"></span>**Proposition 1.** (2.2a)  $\mathcal{B}_{S}$  does not depend on the choice of defining function  $r$ . (2.2b) If  $\psi$  is an automorphism of  $\mathbb{CP}^{\frac{1}{2}}$  then  $\mathscr{B}_s = \psi^* \left( \mathscr{B}_{\psi(S)} \right)$  (where defined).

*Proof.* For [\(2.2a\)](#page-1-0), check that if *r* is replaced by  $\eta \cdot r$  with  $\eta$  non-vanishing then both the numerator and denominator above pick up a factor of  $\eta(p)^3$  at  $p \in S$ .

For [\(2.2](#page-1-0)[b\)](#page-1-1), first recall that automorphisms of  $\mathbb{CP}^2$  have the form

$$
(z_1, z_2) \mapsto \left(\frac{D + Ez_1 + Fz_2}{A + Bz_1 + Cz_2}, \frac{G + Hz_1 + Iz_2}{A + Bz_1 + Cz_2}\right).
$$

 $\left| \right|$ ⎜ ⎜ *A B*  $C$ *D*  $E$   $F$ *𝐺 𝐻 𝐼* ⎞  $\mathbf l$ ⎟ invertible. The group of these automorphisms is generated by the invertible affine

transformations together with the particular transformation

$$
(z_1, z_2) \mapsto \left(\frac{1}{z_1}, \frac{z_2}{z_1}\right);
$$

the transformation law can be verified by straightforward computation in either case.  $\Box$ 

In view of [\(2.2](#page-1-0)[b\)](#page-1-1), the construction of  $\mathcal{B}_{\mathcal{S}}$  also makes sense on a strongly pseudoconvex real hypersurface in  $\mathbb{CP}^2$  – see [Bar, §5.3] for a more directly projective approach to the construction and the transformation law.

**Proposition 2.** If 
$$
S_{\text{sph}}
$$
 is the unit sphere  $\{(z_1, z_2) \in \mathbb{C}^2 : |z_1|^2 + |z_2|^2 = 1\}$  then  $\mathcal{B}_{S_{\text{sph}}} = 0 \cdot \frac{dz_1 \wedge dz_2}{d\overline{z_1} \wedge d\overline{z_2}}$ .

*Proof.* This follows by direct computation with  $r(z_1, z_2) = |z_1|^2 + |z_2|^2 - 1$ .

**Corollary 3.** If  $S_{\text{Heis}}$  is the Heisenberg hypersurface  $\{(z_1, z_2) \in \mathbb{C}^2 : \text{Im } z_2 = |z_1|^2\}$  then  $\mathcal{B}_{S_{\text{Heis}}}$  $0 \cdot \frac{dz_1 \wedge dz_2}{\sqrt{z_1+z_2}}$  $d\overline{z_1} \wedge d\overline{z_2}$ *.*

*Proof.* This can be handled either by direct computation as above or by applying [\(2.2](#page-1-0)[b\)](#page-1-1) to the projective automorphism

$$
\psi : S_{\text{Heis}} \to S_{\text{sph}}
$$

$$
(z_1, z_2) \mapsto \left(\frac{2z_1}{i + z_2}, \frac{i - z_2}{i + z_2}\right).
$$

In the other direction we have the following result.

### **Theorem 4.** *([Jen], [DeTr], [Bol]).*

 $\mathscr{B}_{S}$  vanishes identically if and only if  $S$  is locally a projective image of the unit sphere  $S_{\text{sph}}$  (or *equivalently, of the Heisenberg hypersurface*  $S_{\text{Heis}}$ *).* 

**Proposition 5.** Let S be a smooth strongly pseudoconvex real hypersurface in  $\mathbb{CP}^2$  and let p be a *point in* S. Then there is an automorphism of  $\mathbb{CP}^2$  moving p to  $0 \in \mathbb{C}^2$  so that the transformed S *takes the form*

(2.3) 
$$
\operatorname{Im} z_2 = |z_1|^2 + \beta \operatorname{Re} z_1^2 + O\left(\|(z_1, \operatorname{Re} z_2)\|^3\right)
$$

*near* 0 *with uniquely-determined*  $\beta \in [0, \infty)$ *.* 

*Proof.* See [Bar, Prop. 5] and the following discussion. □

(For projective normalization of higher-order terms see [Ham].) For a hypersurface  $S$  of the form  $(2.3)$  we have (by direct calculation) that

<span id="page-2-1"></span>
$$
\mathcal{B}_{S}(0) = \beta \, \frac{d \, z_1 \wedge dz_2}{d \, \overline{z_1} \wedge d \, \overline{z_2}};
$$

moreover the order of contact between *S* and  $S_{\text{Heis}}$  is  $\begin{cases} \geq 3 & \text{if } \beta = 0 \\ 2 & \text{if } \beta \neq 0 \end{cases}$ 2 if  $\beta \neq 0$ . Thus the *projective-umbilic points* from the end of [§1](#page-0-0) are precisely the points where  $\mathcal{B}_s$  vanishes.

<span id="page-2-0"></span>**Example 6.** The smooth portion  $\{(z_1, z_2) : |z_1|^p + |z_2|^p = 1, z_1 z_2 \neq 0\}$  of the boundary of the unit  $L^p$  ball in  $\mathbb{C}^2$  is locally CR-equivalent to the sphere, using a branch of  $\left( z_1^{2/p} \right)$  $\frac{2}{p}, \frac{2}{p}$ 2 ) , but contains no projective-umbilic points when  $p \neq 2$  since

$$
\mathcal{B}_S = \frac{2 - p}{p} \frac{\overline{z_1 z_2}}{z_1 z_2} \frac{dz_1 \wedge dz_2}{d\overline{z_1} \wedge d\overline{z_2}}
$$

in this case.

 $\Box$ 

#### 3. MAIN RESULT

<span id="page-3-2"></span>**Theorem 7.** If *S* is the boundary of a bounded strongly pseudoconvex complete circular domain  $\int$  *in*  $\mathbb{C}^2$  *then*  $S$  *contains at least one circle of projective-umbilic points.* 

*Proof.* The complete circularity condition implies in particular that *S* intersects each complex line *L* through the origin in one circle  $C_L$ ; since *S* is strongly pseudoconvex, *L* cannot be completely tangent to *S* along  $C_L$ , so in fact *L* intersects *S* transversely along  $C_L$ .

<span id="page-3-0"></span>It follows that we may write

(3.1) 
$$
S \setminus \{z_2 = 0\} = \left\{ (z_1, z_2) : z_2 \neq 0, z_2 \overline{z_2} = e^{\rho(z_1/z_2)} \right\}
$$

where  $\rho$  is a smooth ℝ-valued function on  $\mathbb C$ . Similarly we may write

(3.2) 
$$
S \setminus \{z_1 = 0\} = \left\{ (z_1, z_2) : z_1 \neq 0, z_1 \overline{z_1} = e^{\tilde{\rho}(z_2/z_1)} \right\}.
$$

Setting  $\zeta = z_1/z_2$  we have from [\(3.1\)](#page-3-0) that

<span id="page-3-1"></span>
$$
\mathcal{B}_S = b_S(\zeta) \frac{\overline{z_2}^2}{z_2^2} \frac{dz_1 \wedge dz_2}{d\overline{z_1} \wedge d\overline{z_2}}
$$

where  $b_S(\zeta) = \rho_{\zeta\zeta} - \rho_{\zeta}^2$ *𝜁*  $\rho_{\zeta\overline{\zeta}}$ is ℂ-valued (but not holomorphic). The strong pseudoconvexity of *𝑆*

guarantees that the denominator  $\rho_{\zeta\overline{\zeta}}$  is non-vanishing for  $\zeta \in \mathbb{C}$ .

Using [\(3.2\)](#page-3-1) instead we have the alternate formula

$$
\mathcal{B}_S = \widetilde{b}_S(1/\zeta) \frac{\overline{z_1}^2}{z_1^2} \frac{dz_1 \wedge dz_2}{d\overline{z_1} \wedge d\overline{z_2}}.
$$

Comparing the formulae we find that

$$
b_S(\zeta) = \widetilde{b}_S(1/\zeta) \cdot \frac{\overline{\zeta}^2}{\zeta^2} \stackrel{\zeta \text{ large}}{\approx} \widetilde{b}_S(0) \cdot \frac{\overline{\zeta}^2}{\zeta^2}
$$

Assuming that *S* is not projective-umbilic at points lying on the  $z_1$ -axis we have  $\widetilde{b}_s(0) \neq 0$ .

It follows that the logarithmic integral ∫  $|\zeta|=M$  $db_S$ *𝑏𝑆* ∈ 2*𝜋𝑖*ℤ must equal −8*𝜋𝑖* for *𝑀* large. From Stokes' theorem we now see that  $b_s$  must have zeros in the disk  $|\zeta| < M$ .

# 4. COMMENTS AND EXAMPLES.

**Example 8.** Consider the hypersurface  $S = \{(z_1, z_2) : (|z_1|^2 + |z_2|^2)^2 + |z_1|^4 + |z_2|^4 = 2\}$ . Computation reveals that

$$
\mathcal{B}_S=-\frac{3\overline{z_1^2 z_2^2}}{2\left(|z_1|^4+4|z_1z_2|^2+|z_2|^4\right)}\,\frac{dz_1\wedge dz_2}{d\overline{z_1}\wedge d\overline{z_2}},
$$

so  $\mathcal{B}_{S}$  has double (conjugate) zeros along each axis. In fact, *S* has fourth order contact with  $2|z_1|^2 + |z_2|^2 = 2$  along the  $z_1$ -axis and with  $|z_1|^2 + 2|z_2|^2 = 2$  along the  $z_2$ -axis.

<span id="page-4-1"></span>**Question 9.** *Suppose that 𝑆 ⊂* ℂℙ<sup>2</sup> *is a not-necessarily-circular compact strongly pseudoconvex real hypersurface satisfying the strong*  $\mathbb{C}$ -convexity condition  $|\mathcal{B}_s| < 1$  ([APS, Def. 2.5.10, [Bar],  $885$  2-31) Must S have a projective-umbilic point? *§§5.2-3]). Must 𝑆 have a projective-umbilic point?*

**Example 10.** The answer to the above question is negative if the strong ℂ-convexity condition is dropped. In fact, the example

$$
\left(\log|z_1|\right)^2 + \left(\log|z_2|\right)^2 = \varepsilon^2
$$

from [ESZ] of a compact strongly pseudoconvex hypersurface in  $\mathbb{C}^2$  without CR-umbilic points also has no projective-umbilic points when  $\epsilon$  is small. (The latter claim follows from  $\beta_S = -\frac{\overline{z_1 z_2}}{\overline{z_2 z_3}}$  $\frac{z_1 z_2}{z_1 z_2} (1 +$ 

 $\mathcal{O}(\varepsilon)$ )  $\frac{dz_1\wedge dz_2}{d\overline{z_1}\wedge d\overline{z_2}}$ .)

*Note:* The strong C-convexity condition appearing in Question [9](#page-4-1) implies in particular that the domain bounded by *S* is homeomorphic to the unit ball [APS, Thm. 2.4.2].

<span id="page-4-2"></span>**Remark 11.** The proof of Theorem [7](#page-3-2) given above is essentially topological. In effect, it shows that any Beltrami differential on  $S^3$  that is invariant under rotations  $R_{\theta}$ :  $(z_1, z_2) \mapsto (e^{i\theta_1}z_1, e^{i\theta_2}z_2)$ must vanish along at least one circle.

It will not be possible to resolve Question [9](#page-4-1) by a purely topological argument; in fact, on any smooth real hypersurface in  $\mathbb{C}^2$  we have the nowhere-vanishing Beltrami differential  $\frac{dz_1 \wedge dz_2}{\sqrt{dz_1}}$  $d\overline{z_1} \wedge d\overline{z_2}$ .

<span id="page-4-0"></span>It is worth noting here that most of the results mentioned in  $\S1$  require a proof with genuine geometry, not just topology (though topological arguments often suffice to prove weaker versions).

5. COMPETING CR STRUCTURES WITH THE SAME MAXIMAL COMPLEX SUBSPACE

Let *S* ⊂  $\mathbb{C}^2$  be a smooth connected real hypersurface with defining function *r*. The maximal complex subbundle  $HS \subset TS$  may be described as ker  $(d^c r|_{TS})$  where  $d^c = \frac{\partial - \overline{\partial}}{\partial x^i}$ <br>Suppose that we have an alternate CR structure on S with the same maximal con  $\frac{-\sigma}{2i}$ .

Suppose that we have an alternate  $CR$  structure on  $S$  with the same maximal complex subbundle  $HS$ .

Let  $\omega$  be a nowhere-vanishing 1-form on *S* that is type (1, 0) on *HS* with respect to the alternate CR structure. Then  $\omega$  may be uniquely decomposed as  $\omega' + \omega''$  where  $\omega'$  is type (1,0) on each  $H_p S$  with respect to the original CR structure and  $\omega''$  is type (0,1) on each  $H_p S$  with respect to the original CR structure. We have  $|\omega''| < |\omega'|$  if the orientations on *HS* match and  $|\omega''| > |\omega'|$  if they do not match.

The 2-forms  $d^c r \wedge \omega'$  and  $d^c r \wedge \omega''$  may be extended to forms on a neighborhood of *S* of types (2,0) and (0,2), respectively, with respect to the original CR structure.

Replacing  $\omega$  by  $\tilde{\omega} = \lambda \omega$  (with  $\lambda$  nowhere vanishing) has the effect of multiplying the (2,0)- and (0,2)-forms above by  $\lambda$  along  $S$  so that the ratio is unchanged along  $S$ .

If the orientations on  $HS$  match then to avoid a vanishing denominator we should take the  $(2,0)$ form to be the denominator. By the same reasoning, in the other case we should take the (0,2)-form to be the denominator; this is the situation arising behind the scenes earlier in this paper, where the alternate CR structure is the one induced by projective duality considerations as in §3 of [BaGr], leading to the ratio [\(2.1\)](#page-1-2) above.

The alternate CR structure can also be defined by the orientation choice together with a dilationinvariant family of ellipses in each  $H<sub>n</sub>$ <sup>*S*</sup> which correspond to circles for the alternate structure.

In the case of non-matching orientations the magnitude  $\vert$ major-to-minor axis ratio  $\frac{1+|b(p)|}{1+|b(q)|}$  for the ellipses in  $H_p S$ , while a v  $b(p)$ <sup> $\frac{dz_1\wedge dz_2}{\sqrt{z_1+z_2}}$ </sup>  $d\overline{z_1} \wedge d\overline{z_2}$  $\left| \frac{def}{=} |b(p)| \right| < 1$  determines the  $1 - |b(p)|$ for the ellipses in  $H_p S$ , while a vector  $X \in H_p(S) \setminus \{0\}$  points in the direction of the minor axes precisely when  $b(p) \frac{dz_1 \wedge dz_2}{\sqrt{2\pi}}$  $d\overline{z_1} \wedge d\overline{z_2}$  $(X, Y) > 0$  for some (equivalently, for all)  $Y \in T_p S \setminus H_p S$  – see [Bar, §5.3]. (Here  $T_p S$  is the space of *real* tangent vectors to *S*.) In the case of matching orientations we reach corresponding conclusions starting with  $b(p) \frac{d\overline{z_1} \wedge d\overline{z_2}}{dz_1}$  $\frac{dz_1 \wedge dz_2}{dz_1 \wedge dz_2}$  (again with  $|b(p)| < 1$ .

To provide a concrete illustration we consider a famous example of Rossi [Ros] (see also [Bur]) of a family of competing CR structures on the unit sphere  $S^3$  in  $C^2$ .

The standard CR structure on  $S^3$  can be described by the condition that the CR functions on  $S^3$ are those annihilated by the (complex) tangential vector field  $\overline{L} \stackrel{\text{def}}{=} z_2 \frac{\partial}{\partial \overline{z}}$  $\frac{\partial}{\partial \overline{z}_1} - z_1 \frac{\partial}{\partial \overline{z}_1}$  $\frac{\partial}{\partial \overline{z}_2}$ . The CR functions for the alternate structure (which depends on a real parameter  $t \in (-1, 1)$ ) are those annihilated by  $\overline{L} + tL$ . The two structures share the same  $H_{(z_1, z_2)}S^3 = \{(\gamma \overline{z}_2, -\gamma \overline{z}_2)\}$ :  $\gamma \in \mathbb{C}\}$ , with matching orientation. (Here we are viewing  $H_{(z_1,z_2)}S^3$  as a vector subspace of the real tangent space  $T_{(z_1,z_2)}\mathbb{C}^2$ , which we identify with  $\mathbb{C}^2$ .)

The function  $f = z_1^2$  $x_1^2 + z_2^2$  $\frac{2}{2} + t \left( \frac{-2}{2} \right)$  $\frac{2}{1} + \overline{z}_2^2$ 2 ) is CR for the alternate structure, so the map

$$
d_{(z_1,z_2)}f : H_{(z_1,z_2)}S^3 \to \mathbb{C}
$$
  

$$
(\gamma \overline{z}_2, -\gamma \overline{z}_1) \mapsto \gamma (z_1 \overline{z}_2 - \overline{z}_1 z_2) + t \overline{\gamma} (\overline{z}_1 z_2 - z_1 \overline{z}_2)
$$

is ℂ-linear for the alternate structure. So the ellipses we want are given by

$$
\left|\gamma\left(z_1\overline{z}_2-\overline{z}_1z_2\right)+\overline{\gamma}t\left(\overline{z}_1z_2-z_1\overline{z}_2\right)\right|=C^{\text{constant}}
$$

with the minor axis corresponding to  $\gamma \in i\mathbb{R}$  and the major-to-minor axis ratio equal to  $\frac{1+t}{1-t}$  $1 - t$ .

(The argument above runs into trouble at points where  $d_{(z_1,z_2)}f = 0$  on  $H_{(z_1,z_2)}S^3$ ; this happens in particular when one of the  $z_j$  is a real multiple of the other. However, the conclusions above can still be shown to hold at such points by replacing *f* by  $g = z_1^2$  $\frac{2}{1} - z_2^2$  $\frac{2}{2} - t \left( \overline{z}_1^2 - \overline{z}_2^2 \right)$ 2  $\int$  or by  $h = z_1 z_2 - t \overline{z}_1 \overline{z}_2$ .)

To compare this conclusions to the geometric discussion of Beltrami differentials above we see that we must have  $\frac{1 + |b(p)|}{1 + |b(p)|}$  $\frac{1 + |b(p)|}{1 - |b(p)|} = \frac{1 + t}{1 - t}$  $\frac{1+t}{1-t}$  hence  $|b| \equiv t$  on  $S^3$ . To check the direction of the minor axes we note that the vector  $\{(\gamma \bar{z}_2, -\gamma \bar{z}_1) : \gamma \in \mathbb{C}\}\}\in H_{(z_1, z_2)} S^3$  points in the direction of the minor axes when  $\gamma\left(\overline{z_1z_2}-z_1\overline{z_2}\right)\in\mathbb{R}$ , in particular when  $\gamma=i$ ; thus the vector field  $X \triangleq (i\overline{z_2},-i\overline{z_1})$ describes the minor axes.

Taking *Y* to be the rotational vector field

$$
S^3 \to TS^3
$$

$$
(z_1, z_2) \mapsto (iz_1, iz_2)
$$

we may rewrite *X* and *Y* in operator form

$$
X = i\left(\overline{z}_{2}\frac{\partial}{\partial z_{1}} - \overline{z}_{1}\frac{\partial}{\partial z_{2}} - z_{2}\frac{\partial}{\partial \overline{z}_{1}} + z_{1}\frac{\partial}{\partial \overline{z}_{2}}\right)
$$

$$
Y = i\left(z_{1}\frac{\partial}{\partial z_{1}} + z_{2}\frac{\partial}{\partial z_{2}} - \overline{z}_{1}\frac{\partial}{\partial \overline{z}_{1}} - \overline{z}_{2}\frac{\partial}{\partial \overline{z}_{2}}\right).
$$

Thus  $dz_1 \wedge dz_2(X, Y) = -1 = d\overline{z}_1 \wedge d\overline{z}_2$  and  $\frac{d\overline{z_1} \wedge d\overline{z_2}}{dz_1 \wedge dz_2}(X, Y) > 0$ .

Combining our conclusions, we see that the Beltrami differential for the Rossi example is  $t^{\frac{d\overline{z_1} \wedge d\overline{z_2}}{d}$  $\frac{dz_1\wedge dz_2}{dz_1\wedge dz_2}.$ (Compare Remark [11](#page-4-2) above.)
