Abstract. ARBITRARY PATTERN FORMATION is a widely studied problem in autonomous robot systems. The problem asks to design a distributed algorithm that moves a team of autonomous, anonymous and identical mobile robots to form any arbitrary pattern given as input. The majority of the existing literature investigates this problem for robots with unobstructed visibility. In a few recent works, the problem has been studied in the obstructed visibility model, where the view of a robot can be obstructed by the presence of other robots. However, in these works, the robots have been modelled as dimensionless points in the plane. In this paper, we have considered the problem in the more realistic setting where the robots have a physical extent. In particular, the robots are modelled as opaque disks. Furthermore, the robots operate under a fully asynchronous scheduler. They do not have access to any global coordinate system, but agree on the direction and orientation of one coordinate axis. Each robot is equipped with an externally visible light which can assume a constant number of predefined colors. In this setting, we have given a complete characterization of initial configurations from where any arbitrary pattern can be formed by a deterministic distributed algorithm.

Keywords: Distributed algorithm · Arbitrary Pattern Formation · Leader election · Opaque fat robots · Luminous robots · Asynchronous scheduler

1 Introduction

ARBITRARY PATTERN FORMATION or \mathcal{APF} is a fundamental coordination problem for distributed multi-robot systems. Given a team of autonomous mobile robots, the goal is to design a distributed algorithm that guides the robots to form any specific but arbitrary geometric pattern given to the robots as input. ARBITRARY PATTERN FORMATION is closely related to the LEADER ELECTION problem where a unique robot from the team is to be elected as the leader. In the traditional framework of theoretical studies, the robots are modelled as *autonomous* (there is no central control), *homogeneous* (they execute the same distributed algorithm), *anonymous* (they have no unique identifiers) and *identical* (they are indistinguishable by their appearance) computational entities that can freely move in the plane. Each robot is equipped with sensor capabilities to perceive the positions of other robots. The robots do not have access to any global coordinate system. The robots operate in LOOK-COMPUTE-MOVE (LCM) cycles: upon becoming active, a robot takes a snapshot of the positions of the other robots (LOOK), then computes a destination based on the snapshot (COMPUTE), and then moves towards the destination along a straight line (MOVE).

The ARBITRARY PATTERN FORMATION problem has been extensively studied in the literature in various settings (See [2, 4, 6, 7, 9, 11] and references therein). Until recently, the problem had only been

^{*} The first two authors are supported by NBHM, DAE, Govt. of India and CSIR, Govt. of India, respectively.

studied for robots with unobstructed visibility. In [10], the problem was first considered in the *opaque robots* or *obstructed visibility* model which assumes that the visibility of a robot can be obstructed by the presence of other robots. This is a more realistic model for robots equipped with camera sensors. They also assumed that the robots are equipped with persistent visible lights that can assume a constant number of predefined colors. This is known as the *luminous robot* model, introduced by Peleg [8], where the lights serve both as a medium of weak explicit communication and also as a form of memory. In [10], the robots are first brought to a configuration in which each robot can see all other robots, and then LEADER ELECTION is solved by a randomized algorithm. The first fully deterministic solutions for LEADER ELECTION and ARBITRARY PATTERN FORMATION were given in [3] for robots whose local coordinate systems agree on the direction and orientation of one coordinate axis. However, in both [3,10], the robots were modelled as dimensionless points in the plane. This assumption is obviously unrealistic, as real robots have a physical extent. In this work, we extend the results of [3] to the more realistic *opaque fat robots* model [1, 5]. Furthermore, our algorithm also works for robots with *non-rigid* movements (a robot may stop before it reaches its computed destination), whereas the algorithm of [3] requires robots to have *rigid* movements (a robot reaches its computed destination without any interruption). Also, the total number of moves executed by the robots in our algorithm is asymptotically optimal. The contribution of this paper is summarized in Table 1.

	Robots	Agreement in coordinate system	Scheduler	No. of colors used	Movement	Total no. of moves
[3]	Point	One-axis agreement	ASYNC	6	Rigid	$O(n^2)$
This paper	Fat	One-axis agreement	ASYNC	10	Non-rigid	$\Theta(n)$

Table 1: Comparison of this work with previous ones.

2 Model and Definitions

In this section, we shall formally describe the robot model and also present the necessary definitions and notations that will be used in the rest of the paper.

Robots. We consider a set of $n \geq 3$ autonomous, anonymous, homogeneous and identical fat robots. Each robot is modelled as a disk of diameter equal to 1 unit. The robots do not have access to any global coordinate system, but their local coordinate systems agree on the direction and orientation of the X -axis. They also agree on the unit of length as the diameter of the robots are same and taken as 1 unit.

Lights. Each robot is equipped with an externally visible light which can assume a constant number of colors. Our algorithm will require in total ten colors, namely `off`, `terminal`, `interior`, `failed`, `symmetry`, `ready`, `move`, `switch off`, `leader` and `done`. Initially all robots have their lights set to `off`.

Visibility. The visibility range of a robot is unlimited, but can be obstructed by the presence of other robots. Formally, a point p in the plane is visible to a robot r_i if and only if there exists a point x_i on the boundary of r_i such that the line segment joining p and x_i does not contain any point of any other robot. This implies that a robot r_i can see another robot r_j if and only if there is at least one point on the boundary of r_j that is visible to r_i . Also, if r_i can see any portion of the boundary of r_j , then we assume that it can determine the position of (the center of) r_j .

Look-Compute-Move cycles. The robots, when active, operate according to the so-called LOOK-COMPUTE-MOVE (*LCM*) cycle. In each cycle, a previously idle robot wakes up and executes the following steps. In LOOK, a robot takes the snapshot of the positions of the robots visible to it (represented in its own coordinate system), along with their respective colors. Then in COMPUTE, based on the perceived configuration, the robot performs computations according to a deterministic algorithm to decide a destination point and a color. Finally in MOVE, it sets its light to the decided color and moves towards the destination point. When a robot transitions from one LCM cycle to the next, all of its local memory (past computations and snapshots) are erased, except for the color of the light.

Scheduler. We assume that the robots are controlled by a fully asynchronous adversarial scheduler. The robots are activated independently and each robot executes its cycles independently. The amount of time spent in LOOK, COMPUTE, MOVE and inactive states is finite but unbounded, unpredictable and not same for different robots. As a result, a robot can be seen while moving, and hence, computations can be made based on obsolete information about positions.

Movement. We assume that the robots have *non-rigid* movements. This means that a robot may stop before it reaches its destination. However, there is a fixed $\delta > 0$ so that each robot traverses at least the distance δ unless its destination is closer than δ . The value of δ , however, is not known to the robots. The existence of a fixed δ is necessary, because otherwise, a robot may stop after moving distances $\frac{1}{2}, \frac{1}{4}, \frac{1}{8}, \dots$ and thus, not allowing any robot to traverse a distance of more than 1.

Definitions and Notations. We shall denote the set of robots by $\mathcal{R} = \{r_1, r_2, \dots, r_n\}$, $n \geq 3$. When we say that a robot is at a point p on the plane, we shall mean that its center is at p . For any time t , the configuration of the robots at time t , denoted by $\mathbb{C}(t)$ or simply \mathbb{C} , is a sequence $(p_1(t), p_2(t), \dots, p_n(t))$ of n points on the plane, where $p_i(t)$ is the position of (the center of) the robot r_i at t . At any time t , $r(t).light$ or simply $r.light$ will denote the color of the light of r at t . With respect to the local coordinate system of a robot, positive and negative directions of the X -axis will be referred to as *right* and *left* respectively, and the positive and negative directions of the Y -axis will be referred to as *up* and *down* respectively. Since the robots agree on the X -axis, they agree on horizontal and vertical. They also agree on left and right, but not on up and down. For a robot r , $\mathcal{L}_V(r)$ and $\mathcal{L}_H(r)$ are respectively the vertical and horizontal lines passing through the center of r . We denote by $\mathcal{H}_U^O(r)$ (resp. $\mathcal{H}_U^C(r)$) and $\mathcal{H}_B^O(r)$ (resp. $\mathcal{H}_B^C(r)$) the upper and bottom open (resp. closed) half-planes delimited by $\mathcal{L}_H(r)$ respectively. Similarly, $\mathcal{H}_L^O(r)$ (resp. $\mathcal{H}_L^C(r)$) and $\mathcal{H}_R^O(r)$ (resp. $\mathcal{H}_R^C(r)$) are the left and right open (resp. closed) half-planes delimited by $\mathcal{L}_V(r)$ respectively. For a configuration \mathbb{C} , a subset of robots that are on the same vertical line will be called a *batch*. Thus, any configuration \mathbb{C} can be partitioned into batches B_1, \dots, B_k , ordered from left to right. The vertical line passing through the centers of the robots of a batch will be called the *central axis* of that batch. When we say ‘the distance between a batch B_i and a robot r (resp. another batch B_j)’, we shall mean the horizontal distance between the central axis of B_i and the center of r (resp. central axis of B_j). A robot r belonging to batch B_i will be called *non-terminal* if it lies between two other robots of B_i , and otherwise it will be called *terminal*. Consider any batch B_j whose central axis is \mathcal{S} and a horizontal line \mathcal{T} . Let \mathcal{H}_1 and \mathcal{H}_2 be the closed half-planes delimited by \mathcal{T} . For each $\mathcal{H}_i, i = 1, 2$, consider the distances of the robots on $\mathcal{S} \cap \mathcal{H}_i$ from \mathcal{T} arranged in increasing order. The string of real numbers thus obtained is denoted by λ_i . To make the lengths of the strings λ_1 and λ_2 equal, null elements Φ may be appended to the shorter string. Now the two strings are different if and only if the robots of B_j are not in symmetric positions with respect to \mathcal{T} . In that case, \mathcal{H}_i will be called the *dominant half with respect to \mathcal{T} and B_j* if λ_i is the lexicographically smaller sequence (setting $x < \Phi$ for any $x \in \mathbb{R}$).

Problem Definition. Consider an initial configuration of n fat opaque robots in the Euclidean plane, all having their lights set to `off`. Each robot is given as input, a pattern \mathbb{P} , which is a list of n distinct elements from $\mathbb{R}_{\geq 0}^2 = \{(a, b) \in \mathbb{R}^2 | a, b \geq 0\}$. The ARBITRARY PATTERN FORMATION requires to design a distributed algorithm that guides the robots to a configuration that is similar to \mathbb{P} with respect to translation, reflection, rotation and uniform scaling.

3 The Algorithm

The main result of the paper is Theorem 1. The proof of the ‘only if’ part is the same as in case for point robots, proved in [3]. The ‘if’ part will follow from the algorithm presented in this section.

Theorem 1. *For a set of opaque luminous fat robots with non-rigid movements and having one axis agreement, APF is deterministically solvable if and only if the initial configuration is not symmetric with respect to a line \mathcal{K} which 1) is parallel to the agreed axis and 2) does not pass through the center of any robot.*

For the rest of the paper, we shall assume that the initial configuration $\mathbb{C}(0)$ does not admit the unsolvable symmetry stated in Theorem 1. Our algorithm works in two *stages*, namely *leader election* and *pattern formation from leader configuration*. The first stage is again divided into two phases, namely *Phase 1* and *Phase 2*. In the first stage, a single robot will be elected as the leader of the swarm. Since the robots do not have access to any global coordinate system, they do not agree on how the given pattern \mathbb{P} would be realized in the plane. With the help of the elected leader, the robots can implicitly agree on a common coordinate system. Once an agreement on a common coordinate system is achieved, the robots will arrange themselves to form the given pattern in the agreed coordinate system in the second stage. Since the robots are oblivious, in each LCM cycle, a robot has to infer the current stage or phase from its local view. This is described in Algorithm 1.

Algorithm 1: Arbitrary Pattern Formation

```

Input : The configuration of robots visible to me.
1 Procedure ARBITRARYPATTERNFORMATION()
2   if there is a robot with light set to leader then // stage 2
3     PATTERNFORMATIONFROMLEADERCONFIGURATION()
4   else // stage 1
5     if (the first batch has two robots with light set to terminal) and (the lights of all robots of the
6       second batch are set to same color) and (the distance between the first and second batch is at
7       least  $\frac{n+3}{2}$  units) then
8         PHASE2()
9     else if there is at least one robot with light set to failed, symmetry, ready, move or switch off
10      then
11        PHASE2()
12      else
13        PHASE1()

```

3.1 Leader Election

In the leader election stage, a unique robot r_l will elect itself as leader by setting its light to leader (while the lights of all other robots should be set to `off`). We want the configuration to satisfy some additional properties as well, that will be useful in the second stage of the algorithm. In particular, we want 1) all the non-leader robots to lie inside $\mathcal{H}_R^O(r_l) \cap \mathcal{H}$ where $\mathcal{H} \in \{\mathcal{H}_U^O(r_l), \mathcal{H}_B^O(r_l)\}$, and 2) the distance of any non-leader robot from $\mathcal{L}_H(r_l)$ to be at least 2 units. We shall call this a *leader configuration*, and call r_l the *leader*.

3.2 Phase 1

Since the robots already have an agreement on left and right, if there is a unique leftmost robot, i.e., the first batch has only one robot, then that robot, say r , can identify this from its local view and elect itself as the leader. However, the robot r will not immediately change its light to leader as the additional conditions of a leader configuration might not be yet satisfied. So, it will start executing the procedure `BECOMELEADER()` (See Fig. 1). Only after these conditions are satisfied, r will change its light to leader. However, there might be more than one leftmost robots in the configuration. In the extreme case, all the robots may lie on the same vertical line, i.e., there may be only one batch. So if there are

more than one leftmost robots, the aim of Phase 1 is to move the two terminal robots of the first batch leftwards by the same amount. We also want the distance between (the central axes of) the first batch and second batch in the new configuration to be at least $\frac{n+3}{2}$ units. Therefore, at the end of Phase 1, we shall either have a leader configuration or have at least two batches in the configuration with the first batch having exactly two robots and at least $\frac{n+3}{2}$ units to the left of the second batch. In the second case, the lights of the two robots of the first batch will be set to `terminal`, lights of all robots of the second batch will be set to either `interior` or `off`, and all other robots have lights set to `off`. Due to space restrictions, we will not describe the algorithm here in much detail. A formal pseudocode description of the algorithm is given in Algorithm 2. Further details can be found in Appendix A.1.

Algorithm 2: Phase1

```

1 Procedure PHASE1()
2    $r \leftarrow \text{myself}$ 
3   if  $r.\text{light} = \text{off}$  then
4     if I am in the first batch and I am the only robot in my batch then
5       BECOMELEADER()
6     else if I am in the first batch and I am not the only robot in my batch then
7       if I am terminal then
8          $r.\text{light} \leftarrow \text{terminal}$ 
9       else
10         $r.\text{light} \leftarrow \text{interior}$ 
11     else if there is a robot with light interior on  $\mathcal{L}_V(r)$  then
12       if I am not terminal then
13          $r.\text{light} \leftarrow \text{interior}$ 
14       else if (I am terminal) and (there is exactly one robot  $r'$  in  $\mathcal{H}_L^O(r)$ ) and ( $r'.$ light = terminal) then
15          $r.\text{light} \leftarrow \text{terminal}$ 
16         Move  $\frac{n+3}{2}$  units to the left
17   else if  $r.\text{light} = \text{terminal}$  then
18     if there is a robot on  $\mathcal{L}_V(r)$  with light interior then
19       Move  $\frac{n+3}{2}$  units to the left
20     else if there is a robot on  $\mathcal{L}_V(r)$  with light terminal then
21        $d \leftarrow$  my horizontal distance from the leftmost robot in  $\mathcal{H}_R^O(r)$ 
22       if  $d < \frac{n+3}{2}$  then
23         Move  $\frac{n+3}{2} - d$  units to the left
24     else if there is a robot  $r'$  in  $\mathcal{H}_L^O(r)$  with light terminal then
25        $d \leftarrow$  my horizontal distance from  $r'$ 
26       Move  $d$  units to the left

```

3.3 Phase 2

Assume that at the end of Phase 1, we have $k \geq 2$ batches and exactly two robots r_1^1 and r_2^1 in the first batch B_1 with light `terminal` that are at least $\frac{n+3}{2}$ units to the left of B_2 . So now we are in Phase 2. Let \mathcal{L} be the horizontal line passing through the mid-point of the line segment joining r_1^1 and r_2^1 . Let \mathcal{H}_1 and \mathcal{H}_2 be the two open half-planes delimited by \mathcal{L} such that $r_1^1 \in \mathcal{H}_1$ and $r_2^1 \in \mathcal{H}_2$. Our algorithm will achieve the following. Define $i > 1$ to be the smallest integer such that B_i is either (Case 1) asymmetric with respect to \mathcal{L} , or (Case 2) symmetric with respect to \mathcal{L} , but it has a robot lying on \mathcal{L} . In Case 1, a terminal robot from B_{i-1} will become the leader and in Case 2, the robot from B_i that lies on \mathcal{L} will become the leader. From left to right, terminal robots of different batches will attempt to elect a leader either by electing itself as the leader or by asking a robot of the next batch to become the leader. In particular, when a batch B_j tries to elect leader, its terminal robots will check whether the next batch B_{j+1} is asymmetric or symmetric with respect to \mathcal{L} . In the first case, the terminal robot of B_j lying in the dominant half with respect to \mathcal{L} and B_{j+1} will elect itself as the leader. In the later case, the terminal robots of B_j , using light, will communicate to the robots of B_{j+1} the fact that B_{j+1} is symmetric with respect to \mathcal{L} . If \mathcal{L} passes through the center of a robot of B_{j+1} , then that robot will elect itself as the

leader. Now there are three issues regarding the implementation of this strategy, which we shall discuss in the following three sections.

1. What happens when the robots of B_j are unable to see all the robots of B_{j+1} ?
2. How will the robots ascertain \mathcal{L} from their local view?
3. How will all the conditions of a leader configuration be achieved?

3.3.1 Coordinated Movement of a Batch

When the terminal robots of a batch B_j attempt to elect leader, they need to see all the robots of the next batch B_{j+1} . But since the robots are fat and opaque, a robot may not be able to see all the robots of the next batch (See Fig. 2). However, each robot of two consecutive batches will be able to see all robots of the other batch if the two batches are more than 1 unit distance apart. Recall that at the beginning of Phase 2, the robots of B_1 are at least $\frac{n+3}{2}$ units to the left of the robots of B_2 . Therefore, when the robots of the first batch attempt to elect leader, they are able to see all robots of B_2 . Now consider the case where the terminal robots of $B_j, j > 1$ are trying to elect leader. Therefore, the first $j - 1$ batches must have failed to elect leader. This implies that the first j batches are symmetric with respect to \mathcal{L} and \mathcal{L} does not pass through the center of a robot of the first j batches. After the terminal robots of B_{j-1} fail to elect leader, they will change their lights to `failed` and ask the next batch B_j to try to elect a leader. Then the robots of B_j will move left to position themselves exactly at a distance $1 + \frac{1}{n}$ units from the robots of B_{j-1} . It can be shown that (See the proof of Theorem 6.) B_j will have sufficient space to execute the movement and also, their horizontal distance from the robots of B_{j+1} will be at least 2 units after the movement. So, after the movements, the terminal robots of B_j can see all the robots of B_{j+1} .

However, since the scheduler is asynchronous and the movements are non-rigid, the robots of B_j can start moving at different times, move at different speeds and by different amounts. Then there could be many ways in which our algorithm can fail. For example, suppose that a few robots of B_j have seen the two terminal robots of B_{j-1} with light `failed` and thereafter, have completed their moves in one go, while the rest of the robots of the batch are yet to move. Some of these robots have pending moves, while some may not move at all as they may not see the robots with light `failed` in the new configuration. Now the robots that have completed their moves earlier may now erroneously conclude that these robots belong to B_{j+1} , and one of them may find itself eligible to become leader. Meanwhile, one of the robots with a pending move might complete its move and finds itself eligible to become leader in the new configuration. Thus we may end up with two robots electing themselves as leader. Therefore, we have to carefully coordinate the movements of the batch so that they do not get disbanded. We have to ensure that all the robots of the batch remain vertically aligned after their moves, and also the completion of the moves of the batch as a whole must be detectable. We will need two extra colors for this. When the robots of B_j find two terminal robots of B_{j-1} with light `failed`, they will not immediately move; they will first change their lights to `ready` (See Fig. 3). Having all robots of B_j with light set to `ready` will help these robots to identify their batchmates. On one hand, a robot that moves first will be able to identify the robots from its batch that are lagging behind and also detect when every one has completed their moves. On the other hand, a robot that has lagged behind will be able to remember that it has to move (from its own light `ready`) and determine how far it should move (from robots with light `ready` on its left) even if it can not see the terminal robots of batch B_{j-1} . Therefore, before moving, all robots of B_j must change their lights to `ready`. But they can not verify if all their batchmates have changed their lights as they can not see all the robots of their batch. But the robots of B_{j-1} are able to see all the robots of B_j , and thus can certify this. So when all the robots B_j have changed their lights to `ready`, the terminal robots of B_{j-1} will confirm this by turning their lights to `move`. Only after this, the robots of B_j will start moving. The robots will be able to detect that the movement of the batch has completed by checking that its distance from B_{j-1} is $1 + \frac{1}{n}$ and there are no robots with light `ready` on its right. When it detects that the movement of the batch has completed, it will try to elect leader if it is terminal, otherwise, it will change its light to `off`.

3.3.2 Electing Leader from Local View

When the terminal robots of a batch will attempt to elect leader, they will require the knowledge of \mathcal{L} . Therefore, as different batches try to elect leader from left to right, the knowledge of \mathcal{L} also needs to be propagated along the way with the help of lights. Consider the terminal robots r_1^j and r_2^j of a batch $B_j, j \geq 1$, that are attempting to elect a leader. In order to do so, they need two things: 1) the knowledge of \mathcal{L} , and 2) a full view of the next batch B_{j+1} . First consider the case $j = 1$. The terminal robots of the first batch r_1^1 and r_2^1 (with lights set to `terminal`) obviously have the knowledge of \mathcal{L} as it is the horizontal line passing through the mid-point of the line segment joining them. Also, since r_1^1 and r_2^1 are at least $\frac{n+3}{2}$ units apart from the robots of B_2 , they can see all the robots of B_2 . Now suppose that a batch $B_j, j > 1$, is attempting to elect leader. Then as discussed in the last section, the robots of B_j are horizontally exactly $1 + \frac{1}{n}$ units to the right of the robots of B_{j-1} and at least 2 units to the left of the robots of B_{j+1} . Therefore, r_1^j and r_2^j can see all the robots of both batches B_{j-1} and B_{j+1} . Now since B_j is attempting to elect leader, it implies that the first $j - 1$ batches have failed to break symmetry. Hence, the first j batches are symmetric with respect to \mathcal{L} . In particular, \mathcal{L} passes through the mid-point of the line segment joining the terminal robots of B_{j-1} . Since r_1^j and r_2^j can see the terminal robots of B_{j-1} (having lights set to `move`), they can determine \mathcal{L} .

Now, for a batch $B_j, j \geq 1$, attempting to elect leader, there are three cases to consider. If the robots of B_{j+1} are asymmetric with respect to \mathcal{L} (Case 1), the one of r_1^j and r_2^j which is in the dominant half will change its light to `switch off` and start executing `BECOMELEADER()` (described in the following section). If the robots of B_{j+1} are symmetric with respect to \mathcal{L} and \mathcal{L} passes through the center of a robot r' of B_{j+1} (Case 2), then r_1^j and r_2^j will change their lights to `symmetry`. When r' finds two robots on its left batch with light `symmetry` that are equidistant from it, it will change its light to `switch off` and start executing `BECOMELEADER()`. If the robots of B_{j+1} are symmetric with respect to \mathcal{L} and \mathcal{L} does not pass through the center of any robot of B_{j+1} (Case 3), then r_1^j and r_2^j will change their lights to `failed`. Then the robots of B_{j+1} execute movements as described in the previous section.

3.3.3 Executing BecomeLeader()

When a robot finds itself eligible to become leader, it sets its light to `switch off` and executes `BECOMELEADER()` in order to fulfill all the additional conditions of a leader configuration (See Fig. 4). A robot with light `switch off` will not do anything if it sees any robot with light other than `off` in its own batch or an adjacent batch, i.e., it will wait for those robots to turn their lights to `off` (See line 4 of Algorithm 3). A robot r that finds itself eligible to become leader, is either (Case 1) a terminal robot of a batch, or (Case 2) a middle robot of a batch. The first objective is to move vertically so that all robots are in $\mathcal{H} \in \{\mathcal{H}_V^O(r), \mathcal{H}_B^O(r)\}$ and at least 2 units away from $\mathcal{L}_H(r)$. In case 1, the robot has no obstruction to move vertically. But in case 2, it will have to move horizontally left first. We can show (See the proof of Theorem 6) that it will have enough room to move and place itself at a position where there is no obstruction to move vertically. After the vertical movement, it will have to move horizontally so that all other robots are in $\mathcal{H}_R^O(r)$. But it will not try to do this in one go, as we have to also ensure that all other robots turn their lights to `off`. It will first move left to align itself with its nearest left batch, say B_j . From there it can see all robots of B_{j-1} and B_{j+1} , and it will wait until all robots of B_{j-1} and B_{j+1} turn their lights to `off`. Then it will move to align itself with B_{j-1} and so on. Eventually all the conditions of a leader configuration will be satisfied and it will change its light to `leader`.

Algorithm 3: Phase2

```
1 Procedure PHASE2()
2    $r \leftarrow$  myself
3   if  $r.light \neq$  switch off then
4     if there is a robot with light switch off in my batch or an adjacent batch then
5        $r.light \leftarrow$  off
6     else if  $r.light =$  off or interior then
7       if both terminal robots of my left batch have lights set to failed and the non-terminal robots (if any) have
8         lights set to off then
9            $r.light \leftarrow$  ready
10        else if both terminal robots of my left batch have lights set to symmetry and the non-terminal robots (if
11          any) have lights set to off then
12            if the two terminal robots of my left batch are equidistant from me then
13               $r.light \leftarrow$  switch off
14
15        else if  $r.light =$  terminal then
16          ELECTLEADER()
17        else if  $r.light =$  failed then
18          if all robots of my right batch have their lights set to ready then
19             $r.light \leftarrow$  move
20
21        else if  $r.light =$  ready then
22          if there is a robot  $r'$  in  $\mathcal{H}_L^O(r)$  with light set to ready then
23             $d \leftarrow$  the horizontal distance of  $r'$  from me
24            Move  $d$  units towards left
25          else if both terminal robots of my left batch have lights set to move then
26             $d \leftarrow$  the horizontal distance of my left batch from me
27            if  $d > 1 + \frac{1}{n}$  then
28              Move  $d - 1 - \frac{1}{n}$  units towards left
29            else if  $d = 1 + \frac{1}{n}$  then
30              if there is no robot with light ready in  $\mathcal{H}_R^O(r)$  then
31                if I am terminal then
32                  ELECTLEADER()
33                else
34                   $r.light \leftarrow$  off
35
36        else
37          BECOMELEADER()
38
39 Procedure ELECTLEADER()
40   if I am in the first batch then
41      $\mathcal{L} \leftarrow$  the horizontal line passing through the mid-point of the line segment joining me and the other robot (with
42     light terminal) on  $L_V(r)$

48        $r.light \leftarrow$  symmetry
49     else
50        $r.light \leftarrow$  failed
51   else if I am in the dominant half with respect to  $\mathcal{L}$  and my right batch then
52      $r.light \leftarrow$  switch off
```

3.4 Pattern Formation from Leader Configuration

In a leader configuration, the robots can reach an agreement on a common coordinate system. All non-leader robots in a leader configuration lie on one of the open half-planes delimited by the horizontal line passing through the leader r_l . This half-plane will correspond to the positive direction of Y -axis or ‘up’. Therefore, we have an agreement on ‘up’, ‘down’, ‘left’ and ‘right’. Now the origin will be fixed at a point such that the coordinates of r_l are $(0, -2)$. Now the given pattern can be embedded on the plane with respect to the common coordinate system. Let us call these points the *target points*. Order these points as t_0, t_1, \dots, t_{n-1} from top to bottom, and from right to left in case multiple robots on the same

horizontal line (See Fig. 5b). Order the robots as $r_l = r_0, r_1, \dots, r_{n-1}$ from bottom to up, and from left to right in case multiple robots on the same horizontal line (See Fig. 5a). The non-leader robots will move sequentially according to this order and place themselves on $\mathcal{L}_H(r_l)$. Then sequentially r_1, \dots, r_{n-1} will move to the target points t_0, \dots, t_{n-2} , and finally r_0 will move to t_{n-1} . Pseudocode of the algorithm is given in Algorithm 4 and further details are in Appendix B.

Algorithm 4: Pattern Formation from Leader Configuration

```

Input : The configuration of robots visible to me.
1 Procedure PATTERNFORMATIONFROMLEADERCONFIGURATION()
2    $r \leftarrow$  myself
3    $r_l \leftarrow$  the robot with light leader
4   if  $r.light = \text{off}$  then
5     if  $(r_l \in \mathcal{H}_B^O(r))$  and (there is no robot in  $\mathcal{H}_B^O(r) \cap \mathcal{H}_U^O(r_l)$ ) and ( $r$  is leftmost on  $\mathcal{L}_H(r)$ ) then
6       if there are no robots on  $\mathcal{L}_H(r_l)$  other than  $r_l$  then
7         if there is a robot with light done then
8           if I am at  $t_{n-2}$  then
9              $r.light \leftarrow$  done
10          else Move to  $t_{n-2}$ 
11        else
12          Move to  $(1, -2)$ 
13        else if there are  $i$  robots on  $\mathcal{L}_H(r_l)$  other than  $r_l$  at  $(1, -2), \dots, (i, -2)$  then
14          Move to  $(i + 1, -2)$ 
15        else if there are  $i$  robots on  $\mathcal{L}_H(r_l)$  other than  $r_l$  at  $(n - i, -2), \dots, (n - 1, -2)$  then
16          if I am at  $t_{n-i-2}$  then
17             $r.light \leftarrow$  done
18          else Move to  $t_{n-i-2}$ 
19        else if  $r_l \in \mathcal{L}_H(r)$  and  $\mathcal{H}_U^O(r)$  has no robots with light off then
20          if I am at  $(i, -2)$  then
21            Move to  $t_{i-1}$ 
22          else if  $r.light = \text{leader}$  then
23            if there are no robots with light off then
24              if I am at  $t_{n-1}$  then
25                 $r.light \leftarrow$  done
26              else Move to  $t_{n-1}$ 
27            else Move to  $t_{n-1}$ 
28          else Move to  $t_{n-1}$ 
29

```

4 Conclusion

Using 4 extra colors, we have extended the results of [3] to the more realistic setting of fat robots with non-rigid movements and also improved the move complexity to $\Theta(n)$, which is asymptotically optimal. Techniques used in Phase 2 of our algorithm can be used to solve LEADER ELECTION without movement for luminous opaque point robots for any initial configuration where LEADER ELECTION is solvable in full visibility model, except for the configuration where all robots are collinear. An interesting question is whether there is a no movement LEADER ELECTION algorithm for (luminous and opaque) fat robots. Another open question is whether it is possible to solve \mathcal{APF} for opaque (point or fat) robots with only agreement in chirality.

A Correctness of Stage 1

For the correctness proofs, we shall use the notion of a *stable configuration* from [3]. Denote the position of a robot r at time t to be $r(t)$. Suppose that a robot r at p takes a snapshot at time t_1 . Based on this snapshot, suppose that it decides to change its light (Case 1) or move to a different point (Case 2) or both (Case 3). In case 1, assume that it changes its light at time $t_2 > t_1$. In case 2, assume that it starts moving at time $t_3 > t_1$. When we say that it starts moving at t_3 , we shall mean that $r(t_3) = p$, but $r(t_3 + \epsilon) \neq p$ for sufficiently small $\epsilon > 0$. For case 3, assume that r changes its light at $t_2 > t_1$ and starts moving at $t_3 > t_2$. Then we say that r has a *pending move* at t if $t \in (t_1, t_2)$ in case 1 or $t \in (t_1, t_3]$ in case 2 and 3. A robot r is said to be *stable* at time t , if r is stationary and has no pending move at t . A configuration at time t is said to be a *stable configuration* if every robot is stable at t . Also, a configuration at time t is said to be a *final configuration* if

1. every robot at t is stable,
2. any robot taking a snapshot at t will not decide to move or change its color.

The aim of the leader election stage is to form a *leader configuration*. Formally, we define a leader configuration to be a stable configuration in which there is a unique robot r_l such that

1. $r_l.light = \text{leader}$,
2. $r.light = \text{off}$ for all $r \in \mathcal{R} \setminus \{r_l\}$,
3. there is $\mathcal{H} \in \{\mathcal{H}_U^O(r_l), \mathcal{H}_B^O(r_l)\}$ such that $r \in \mathcal{H}_R^O(r_l) \cap \mathcal{H}$ for all $r \in \mathcal{R} \setminus \{r_l\}$,
4. distance of any robot of $\mathcal{R} \setminus \{r_l\}$ from $\mathcal{L}_H(r_l)$ is at least 2 units.

In this section, we shall prove Theorem 2. It will follow from Theorem 3, Theorem 4, Theorem 5 and Theorem 6, whose proofs are given in the following subsections.

Theorem 2. *For any initial configuration $\mathbb{C}(0)$ which is not symmetric with respect to a line \mathcal{K} such that 1) \mathcal{K} is parallel to the X -axis and 2) \mathcal{K} is not passing through the center of any robot, $\exists T_1 > 0$ such that $\mathbb{C}(T_1)$ is a leader configuration.*

A.1 Correctness of Phase 1

Theorem 3. *If the first batch of $\mathbb{C}(0)$ has exactly one robot, then $\exists T_1 > 0$ such that $\mathbb{C}(T_1)$ is a leader configuration.*

Proof. Let r be the robot in the first batch. From its local view, r will find that it is the unique leftmost in the configuration and start executing BECOMELEADER(), i.e., it will move vertically until all other robots are in $\mathcal{H}_R^O(r) \cap \mathcal{H}$, where $\mathcal{H} \in \{\mathcal{H}_U^O(r), \mathcal{H}_B^O(r)\}$ and the distance of any robot of $\mathcal{R} \setminus \{r\}$ from $\mathcal{L}_H(r)$ is at least 2 units.

Case 1 If there is no obstruction to move vertically in both directions ('up' and 'down'), it will move 'down' according to its local coordinate system.

Case 2 If there is exactly one direction where there is no obstruction to move vertically, then it will move in that direction accordingly.

Case 3 If there is obstruction in both directions, then it will have to first move left (See Fig. 1).

When the required condition is achieved, r will change its light to `leader` at some time $T_1 > 0$. It is easy to see that all other robots will remain stable in $[0, T_1]$. So, $\mathbb{C}(T_1)$ is the required leader configuration. \square

Theorem 4. *If the first batch of $\mathbb{C}(0)$ has exactly two robots, then $\exists T' > 0$ such that $\mathbb{C}(T')$ is a stable configuration where*

Fig. 1: a) Execution of `BECOMELEADER()` by the unique leftmost robot r . b) The leader configuration after r changes its light to leader.

1. the first batch has exactly two robots with lights set to `terminal`,
2. the robots of all other batches have their lights set to `off`,
3. the distance between the first and the second batch is at least $\frac{n+3}{2}$ units.

Proof. Let r_1 and r_2 be the two robots of the first batch of $\mathbb{C}(0)$. After some time, both of them will change their lights to `terminal`. Notice that the robots do not move until both of them change their lights. If the distance d between the first and the second batch is already at least $\frac{n+3}{2}$ in $\mathbb{C}(0)$, then the robots do not need to move and we are done. So let $d < \frac{n+3}{2}$. Then the robots r_1 and r_2 will have to move $\frac{n+3}{2} - d$ units to the left, to the points P_1 and P_2 respectively, so that their distance from the second batch becomes exactly $\frac{n+3}{2}$. We will show that the algorithm will successfully bring the robots stationary at the points P_1 and P_2 .

Suppose that the robots take snapshots at times $t_1 \leq t_2 \leq \dots$. We shall show that if $r_i \in \{r_1, r_2\}$ takes a snapshot at t_k , then it will not decide (instructed by Algorithm 2) to move beyond P_i . Without loss of generality, assume that r_1 takes snapshot at t_1 . Notice that if the second batch is too close to the first batch, r_1 and r_2 may not be able to correctly identify the second batch (See Fig. 2). So r_1 will decide to move $\frac{n+3}{2} - d_1$ units left, where d_1 is its horizontal distance from the leftmost robot (that it can see) on its right. Notice that $d_1 \geq d$ (where d is its distance from the actual second batch), and hence, $\frac{n+3}{2} - d_1 \leq \frac{n+3}{2} - d$. So r_1 does not decide to move beyond P_1 . Suppose that the same is true up to the $(k-1)$ th snapshot. Suppose $r_i \in \{r_1, r_2\}$ takes the snapshot at t_k and at that time, its distance from the (actual) second batch of $\mathbb{C}(0)$ is d' .

Case A1 The other robot r_j (with light set to `terminal`) is on $\mathcal{L}_V(r_i)$. If $d' = \frac{n+3}{2}$, it will not move. Otherwise, by the same argument as earlier, r_i will not decide to move beyond P_i .

Case A2 The other robot r_j (with light set to `terminal`) is on $\mathcal{H}_R^O(r_i)$. In this case, r_i will decide not to move.

Case A3 The other robot r_j (with light set to `terminal`) is on $\mathcal{H}_L^O(r_i)$. In this case, r_i will decide to move left to vertically align itself with r_j . By our assumption, r_j is not beyond P_j . So r_i has not decided to move beyond P_i .

Now we show that if r_i at some time t is stationary and its distance d' from the second batch (of $\mathbb{C}(0)$) is less than $\frac{n+3}{2}$, then it will decide to move towards P_i at some time after t . Suppose that it takes the first snapshot after t at t_k .

Fig. 2: The first three batches of a configuration, where $B_1 = \{r_1, r_2\}$, $B_2 = \{r_3\}$ and $B_3 = \{r_4, r_5\}$. Here, r_1 can not see r_3 . Therefore, r_1 thinks that $\{r_4, r_5\}$ is the second batch.

Case B1 The other robot r_j (with light set to `terminal`) is on $\mathcal{L}_V(r_i)$. Of course, it will decide to move left in this case.

Case B2 The other robot r_j (with light set to `terminal`) is on $\mathcal{H}_R^O(r_i)$. In this case, r_i will decide not to move. Then after finite time, r_j will overtake r_i or stop on $\mathcal{L}_V(r_i)$. In either case, r_i will decide to move left.

Case B3 The other robot r_j (with light set to `terminal`) is on $\mathcal{H}_L^O(r_i)$. Clearly, r_i will decide to move left to vertically align itself with r_j .

So, we have shown that each $r_i, i = 1, 2$ gradually moves towards P_i and never decides to move beyond P_i . Therefore both will eventually reach P_i and remain stationary. Also observe that during this process, all the other robots remain stable. Therefore, we shall obtain the required configuration at some time $T' > 0$. \square

Theorem 5. *If the first batch of $\mathbb{C}(0)$ has more than two robots, then $\exists T' > 0$ such that $\mathbb{C}(T')$ is a stable configuration where*

1. *the first batch has exactly two robots with lights set to `terminal`,*
2. *the robots of the second batch have their lights set to `interior`,*
3. *the robots of all other batches have their lights set to `off`,*
4. *the distance between the first and the second batch is exactly $\frac{n+3}{2}$ units.*

Proof. Let r_1 and r_2 be the two terminal robots of the first batch of $\mathbb{C}(0)$. We will first show that both robots will start moving after some finite time. Let r'_1 and r'_2 be the two non-terminal robots of the first batch that are adjacent to r_1 and r_2 respectively ($r'_1 = r'_2$, if there are exactly three robots in the batch). It is easy to see that one of the robots, say r_i will start moving. It suffices to argue for the situation where r_i starts moving before the other terminal robot r_j wakes up. Notice that since r_i starts moving, r'_i must have set its light to `interior`. Then the algorithm ensures that (See line 13 of Algorithm 2) eventually r'_j must also change its light to `interior`. So when r_j takes snapshot, it finds that the conditions in line 24 of Algorithm 2 are satisfied, and hence will decide to move.

Notice that in this case, our algorithm asks the robots to move $\frac{n+3}{2}$ units. This is because, in this case, the non-terminal robots of the first batch would be the second batch of the desired configuration.

Arguing similarly as in the proof of Theorem 3, we can show that they will be able to do so. Also, it is easy to see that all non-terminal robots of the first batch of $\mathbb{C}(0)$ will eventually turn their lights to `interior`, but will stay stationary throughout the process. All the other robots will also remain stable during the process. Hence, we shall obtain the required configuration at some time $T' > 0$. \square

A.2 Correctness of Phase 2

Theorem 6. *If $\mathbb{C}(T')$ is the configuration from Theorem 3 or Theorem 4, then $\exists T_1 > T'$ such that $\mathbb{C}(T_1)$ is a leader configuration.*

Proof. We assumed that $\mathbb{C}(0)$ is not symmetric with respect to any line that is parallel to the X -axis and does not pass through the center of any robot. The same should be true for $\mathbb{C}(T')$ because it is obtained from $\mathbb{C}(0)$ by moving the two terminal robots of the first batch horizontally by equal amounts. So, in particular, if \mathcal{L} is the horizontal line passing through the mid-point of the line segment joining the terminal robots of the first batch of $\mathbb{C}(T')$, then either $\mathbb{C}(T')$ is asymmetric with respect to \mathcal{L} or $\mathbb{C}(T')$ is symmetric with respect to \mathcal{L} , but there is a robot whose center lies on \mathcal{L} . So there is at least one batch that is either asymmetric with respect to \mathcal{L} or symmetric with respect to \mathcal{L} , but it has a robot whose center lies on \mathcal{L} . Let B_i be the first such batch. Obviously, $i > 1$.

We have discussed in Section 3.3 how different batches from left to right will sequentially try to elect a leader. Obviously, B_{i-1} will be successful. If (Case 1) B_i is asymmetric with respect to \mathcal{L} , then one of the terminal robots of B_{i-1} will start executing `BECOMELEADER()`, while if (Case 2) B_i is symmetric with respect to \mathcal{L} , then the terminal robots of B_{i-1} will change their lights to `symmetry` and the robot $r \in B_i$ lying on \mathcal{L} will start executing `BECOMELEADER()`.

We have to show that each of B_1, \dots, B_{i-1} have enough space to successfully execute the instructions of the algorithm. We shall show that when the terminal robots of $B_j, j \geq 1$ call `ELECTLEADER()`, the distance between B_j and B_{j+1} will be at least 2 units. This will ensure the following:

1. the robots of B_j can fully see the batch B_{j+1} ,
2. if the terminal robots of B_j fail to elect leader and turn their lights to `failed`, the robots of B_{j+1} will be able to see this and also will be able to move left and place themselves $1 + \frac{1}{n}$ units apart from B_j ,
3. if the middle robot of B_{j+1} is to become leader, it can move 1 unit to the left so that there is no obstruction to move vertically.

This is obvious for $j = 1$, because B_1 is $\frac{n+3}{2} > 2$ units away from B_2 . Now consider a batch $B_j, 1 < j \leq i - 1$ calling `ELECTLEADER()`. Initially the distance between B_1 and B_2 was at least $\frac{n+3}{2}$ and then each batch $B_l, 1 < l \leq j$, have moved left and placed themselves exactly $1 + \frac{1}{n}$ units apart from B_{l-1} . This implies that the batch B_j has moved at least $\frac{n+3}{2} - (j-1)(1 + \frac{1}{n})$. So, after the movement, the distance between B_j and B_{j+1} is at least $\frac{n+3}{2} - (j-1)(1 + \frac{1}{n})$. Now note that each B_1, \dots, B_j is symmetric with respect to \mathcal{L} and center of no robot of these batches lie on \mathcal{L} . Therefore, each B_1, \dots, B_j has at least 2 robots. So, $2j < n \Rightarrow j < \frac{n}{2}$. Therefore, the required distance between B_j and B_{j+1} is

$$\begin{aligned} &\geq \frac{n+3}{2} - (j-1)\left(1 + \frac{1}{n}\right) \\ &> \frac{n+3}{2} - \left(\frac{n}{2} - 1\right)\left(1 + \frac{1}{n}\right) \\ &= 2 + \frac{1}{n} \end{aligned}$$

When a robot finds itself eligible to become leader, it sets its light to `switch off` and starts executing `BECOMELEADER()`. We have not given any pseudocode for `BECOMELEADER()`. The execution

of `BECOMELEADER()` for a robot with `light off` was described in the proof of Theorem 3. An informal description of the process for a robot with `light switch off` was given in Section 3.3.

In Case 1, a terminal robot r of B_{i-1} will start executing `BECOMELEADER()`. Obviously there is one vertical direction for r to move without any obstruction. However, in Case 2, unless B_i has exactly one robot, the middle robot r of B_i has both vertical directions blocked. So, r will move 1 unit to the left and there will be no obstruction to move vertically. So in either case, r will move vertically and eventually all other robots will be in $\mathcal{H} \in \{\mathcal{H}_V^O(r), \mathcal{H}_B^O(r)\}$ and the distance of any robot of $\mathcal{R} \setminus \{r\}$ from $\mathcal{L}_H(r)$ will be at least 2 units. Then r will sequentially move to the central axes of the batches on its left and all robots that having light set to any color other than `off`, will turn them back to `off`.

However, there can be a complication regarding the first batch B_1 because, as we shall see, there is a possibility that they might start executing the algorithm for Phase 1. Notice that when r starts executing `BECOMELEADER()`, the two robots r_1^1 and r_2^1 of B_1 have their lights set to `move`. Notice that they will change their light to `off`, only when r aligns itself with B_2 at some time t_1 (See line 4 of Algorithm 3). So, upto time t_1 , r_1^1 and r_2^1 with lights `move` will remain stable. After t_1 , they will change their lights to `off`. After this, r will start moving to the left. At some time t_2 , r will become aligned with r_1^1 and r_2^1 . Clearly, r_1^1 and r_2^1 will remain stable in $[t_1, t_2]$. In $\mathbb{C}(t_2)$, one of r_1^1 and r_2^1 , say r_1^1 , can not see r . So, if r_1^1 takes a snapshot at t_2 , it will decide to turn its light to `terminal` according to Algorithm 2. However, r_2^1 will stay stable as it does not loose sight of r with `light switch off`. Hence, it does not execute Algorithm 2. Recall that a robot with `light terminal` decides to move only if it finds another robot with `light terminal` or `interior`. So, r_1^1 will not move. When r moves further left, r_1^1 will again see it and will change its light to `off`. Therefore, we shall obtain a leader configuration at some time T_1 . \square

(a) The batch B_3 is $1 + \frac{1}{n}$ units to the right of B_2 . The terminal robots r_1^3, r_2^3 of B_3 have change their lights to failed. However, the robot r of B_3 still has its light set to ready.

(b) The robots of B_4 waits until r changes its light to off.

(c) The robots of B_4 are changing their lights to ready. The terminal robots r_1^3, r_2^3 of B_3 will wait for all the robots of B_4 to change their lights.

(d) After all the robots of B_4 change their lights to ready, r_1^3 and r_2^3 change their lights to move.

(e) After r_1^3 and r_2^3 change their lights to move, the robots of B_4 start moving. Here r'' has not yet started. If it takes a snapshot of this configuration, it will decide to align itself with r' .

(f) Eventually the robots of B_4 will stop $1 + \frac{1}{n}$ units to the right of B_3 .

Fig. 3: Coordinated movement of a batch in Phase 2.

(a) (Case 1) r finds itself in the dominant half and changes its light to `switch off`. Two robots in its batch, r' and r'' , still have their lights set to `ready`.

(b) (Case 1) r starts moving after r_1^3 , r_2^3 and r' have changed their lights to `off`. But r can not see r'' which is yet to change its light.

(c) (Case 2) r changes its light to `switch off` as r_1^4 and r_2^4 change their lights to `symmetry`.

(d) (Case 2) r_1^4 and r_2^4 change their lights to `off`. Then r will move horizontally left and then vertically.

(e) When r aligns itself with B_3 all robots of B_2 and B_4 can see it. So, any robot of B_2 and B_4 with light not set to `off` will change its light to `off`.

(f) When r aligns itself with B_1 , r_1^1 thinks that it is in Phase 1, and changes its light to `terminal`. However, when r moves further left, r_1^1 will change its light back to `off`.

B Correctness of Stage 2

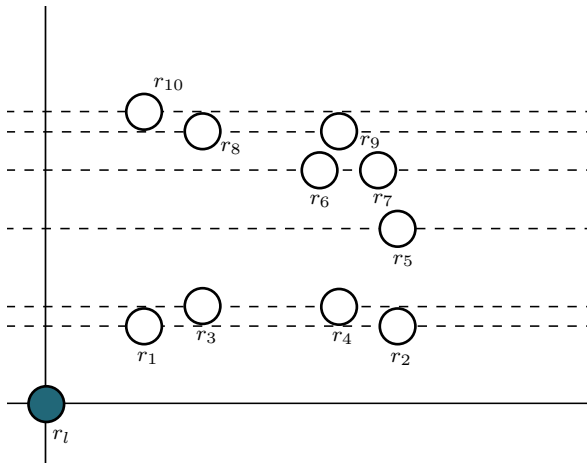

Theorem 7. *If $\mathbb{C}(T_1)$ is a leader configuration, then $\exists T_2 > T_1$ such that $\mathbb{C}(T_2)$ is a final configuration similar to the given pattern.*

Proof. Ordering of the robots and the target points are shown in Fig. 5a and Fig. 5b respectively. We shall first show that the non-leader robots r_1, \dots, r_{n-1} will move sequentially and place themselves on $\mathcal{L}_H(r_l)$ so that at some $T'' > T_1$, we shall have $r_0 = r_l, r_1, \dots, r_{n-1}$ at $(0, -2), (1, -2), \dots, (n-1, -2)$ (See Fig. 5d). At the beginning, r_1 will find that the conditions of lines 5 and 6 (in Algorithm 4) are satisfied, while that of line 7 does not hold. So, it will decide to move to $(1, -2)$. Now suppose that $r_0 = r_l, r_1, \dots, r_i$ ($i \geq 1$) are at $(0, -2), (1, -2), \dots, (i, -2)$, then r_{i+1} will find that the condition of line 14 is satisfied and therefore will decide to move to $(i+1, -2)$.

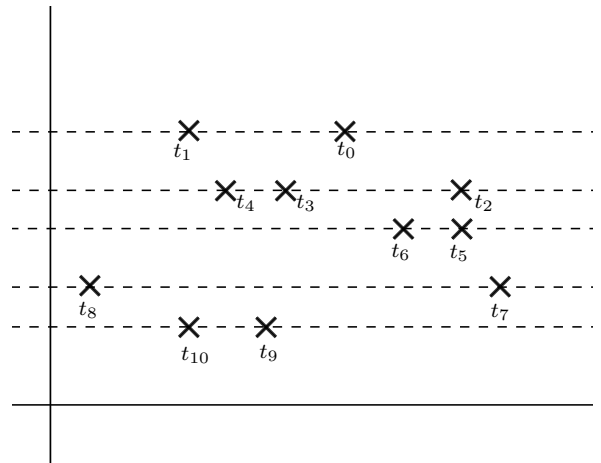

Notice that when any robot $r_j, 1 \leq j \leq n-1$, is moving, even if its move is interrupted due to the non-rigid movement assumption, it will again decide to move to $(j, -2)$ in the next cycle. Also, during the move, no other robot will decide to move. This is because 1) (if $j < n-1$) for r_{j+1}, \dots, r_{n-1} , the condition of line 5 does not hold, 2) (if $j > 1$) for r_1, \dots, r_{j-1} , the condition of line 21 does not hold and 3) for r_l , the condition of line 25 does not hold. Also notice that since the robots have a physical extent, depending on the starting position and destination, a robot may not be able to move to its destination linearly in one go. In that case, it will move in a piecewise linear path (with at most three segments in case of rigid movement) as shown in Fig. 5c. In that case, the ‘Move to $(j, -2)$ ’ instructions in the pseudocode should be understood accordingly. Therefore, at some $T'' > T_1$, we shall have a stable configuration with $r_0 = r_l, r_1, \dots, r_{n-1}$ at $(0, -2), (1, -2), \dots, (n-1, -2)$.

Now we shall show that there is $T_2 > T''$, such that $\mathbb{C}(T_2)$ is a final configuration similar to the given pattern. Notice that in this configuration, the agreement in ‘up’ and ‘down’ is lost. When r_1 takes a snapshot for the first time after T'' , it finds the conditions of line 21 to be true as both $\mathcal{H}_Y^O(r_1)$ and $\mathcal{H}_B^O(r_1)$ (according to its own notion of ‘up’ and ‘down’) has no robots. Since r_1 can see r_l , it will take the center of r_l as $(0, -2)$ and fix the positive direction of Y -axis according to its own notion of ‘up’, compute the point t_0 in that coordinate system and move to that point. After the move, it will turn its light to done. Now suppose that r_1, \dots, r_i ($i \geq 1$) are at t_0, \dots, t_{i-1} with light set to done. Obviously, here r_{i+1} will have no ambiguity regarding the Y -axis. So, r_{i+1} will find the conditions of line 21 to be true, compute the point t_i in the agreed coordinate system and move accordingly.

As before, the movements of the robots may not be linear due to their physical extent (See Fig. 5e). The move of any robot $r_j, 1 \leq j \leq n-1$, may be interrupted due to the non-rigid movement assumption. The ordering of the target points are such that when it takes snapshot in the next cycle, it will be able to see all the robots on $\mathcal{L}_H(r_l)$ and hence, will find the condition of line 16 holding (with $i = n-j-1$). So, it will recompute t_{j-1} and move accordingly. Now we shall argue that no other robot will decide to move during the move of any robot $r_j, 1 \leq j \leq n-1$. This is because during the movement of any robot r_j , all the robots on $\mathcal{L}_H(r_l)$ will be able to see it with light set to `off`. Therefore, 1) (if $j < n-1$) for r_{j+1}, \dots, r_{n-1} , the condition of line 21 does not hold, and 2) for r_l , the condition of line 25 does not hold. Also, (if $j > 1$) for r_1, \dots, r_{j-1} , their lights are set to done and hence, they will remain stable. Now, only after all of r_1, \dots, r_{n-1} have completed their moves and turned their lights to done, $r_l = r_0$ will find condition of line 25 to hold. Then r_0 will move towards t_{n-1} . If it stops in between, it can identify r_{n-1} from its local view. Therefore, it knows the points t_{n-2} on the plane and knows its coordinate in the agreed coordinate system from the given input. From this it can recompute t_{n-1} and hence will eventually reach there. Therefore, the given pattern is formed at some $T_2 > T_1$. \square

(a) A leader configuration with the leader r_l with light leader at $(0, -2)$ in the agreed coordinate system.

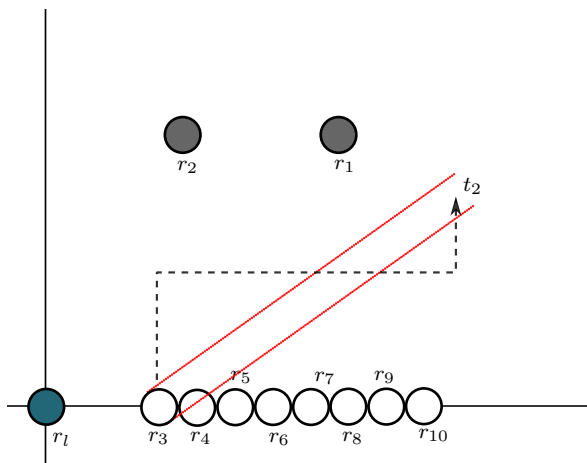

(b) The pattern \mathbb{P} embedded in the agreed coordinate system.

(c) Movement of r_8 to $\mathcal{L}_H(r_l)$.

(d) $r_0 = r_l, r_1, \dots, r_{n-1}$ are at $(0, -2), (1, -2), \dots, (n-1, -2)$.

(e) Movement of r_3 to t_2 .

(f) Movement of r_0 to t_{10} .

C Efficiency of the Algorithm

We shall study the efficiency of the algorithm in terms of the total number of moves executed by all the robots in the team. For the efficiency analysis, we shall consider rigid movements and semi-synchronous scheduler. That is, we shall assume the following.

1. Time is logically divided into global rounds. In each round, a finite but non-zero number of the robots are activated. Every robot is activated infinitely often.
2. In each round, all activated robots take the snapshots at the same time, and then perform their moves simultaneously, and completes their moves before the end of the round. As a result, no robot r sees another robot r' while r' is moving.
3. Each robot is able to reach its computed destination without any interruption.

In this setting, we shall calculate the total number of moves required, in the worst case, in order to reach the final configuration. In Stage 1, all robots, except the one that eventually becomes the leader, execute $O(1)$ moves each. The robot that becomes the leader, will need $\Theta(n)$ moves, in the worst-case, while executing BECOMELEADER(). In Stage 2, it is easy to see that all the robots need $O(1)$ moves each. Therefore, the total number of moves executed by all the robots in the team is $\Theta(n)$. This is also asymptotically optimal. To see this, consider an initial configuration where all robots are collinear. Then if the pattern to be formed does not have three collinear robots, then at least $n - 2$ robots need to move. So, the total number of moves required to solve \mathcal{APF} is $\Omega(n)$. Therefore, we can conclude as the following.

Theorem 8. *Algorithm 1 solves \mathcal{APF} in asymptotically optimal number of moves.*
