A GCICA Grant-Free Random Access Scheme for M2M Communications in Crowded Massive MIMO Systems

Huimei Han[1], Lushun Fang[1], Weidang Lu[1], Wenchao Zhai[2], Ying Li[3], Jun Zhao[4]

***Abstract*—A high success rate of grant-free random access scheme is proposed to support massive access for machine-to-machine communications in massive multiple-input multiple-output systems. This scheme allows active user equipments (UEs) to transmit their modulated uplink messages along with super pilots consisting of multiple sub-pilots to a base station (BS). Then, the BS performs channel state information (CSI) estimation and uplink message decoding by utilizing a proposed graph combined clustering independent component analysis (GCICA) decoding algorithm, and then employs the estimated CSIs to detect active UEs by utilizing the characteristic of asymptotic favorable propagation of massive MIMO channel. We call this proposed scheme as GCICA based random access (GCICA-RA) scheme. We analyze the successful access probability, missed detection probability, and uplink throughput of the GCICA-RA scheme. Numerical results show that, the GCICA-RA scheme significantly improves the successful access probability and uplink throughput, decreases missed detection probability, and provides low CSI estimation error at the same time.**

***Index Terms*—Grant-free random access, independent component analysis (ICA), massive MIMO, M2M communications.**

I. INTRODUCTION

THE machine-to-machine (M2M) communications are centered on the intelligent interaction of user equipments (UEs) without human intervention, which is the enabler for the Internet of Things (IoT) to achieve the envision of the "Internet of Everything" [1]–[4]. In recent years, M2M communications develop rapidly and have been applied to many scenarios, such as smart medical, smart vehicle, smart logistics, etc. Cisco visual networking index and forecast predicts that there will be around 28.5 billion connected UEs by 2022 [5]. The

massive multiple-input multiple-output (MIMO) technology, which achieves significant improvements in energy and spectral efficiency and can serve massive UEs in the same time-frequency resource, is well suited for M2M communications [6]–[8].

For M2M communications in massive MIMO systems, random access procedure is a critical step to initiate a data transmission [9], [10]. Since payload data is usually in small size and the number of UEs in a cell is envisioned in the order of hundreds or thousands in M2M communications [11], random access procedure utilized in the long term evolution (LTE) network may induce excessive signaling overhead and cannot support massive access [9], [12].

Researchers are exploring new random access schemes for M2M communications in massive MIMO systems, and the grant-based random access schemes have been proposed in recent years. E. Björnson *et al.* proposed a strongest-user collision resolution (SUCRe) scheme, which allocates pilots to active UEs with largest channel gain among the contenders [13]. However, the number of successful accessing UEs decreases with the increase of the number of contenders [14]. To improve the pilot resource utilization of the SUCRe scheme, SUCR combined idle pilots access (SUCR-IPA) scheme was proposed in [15], where the weaker UEs randomly select idle pilots to increase the number of successful accessing UEs. A user identity-aided pilot access scheme was proposed for massive MIMO with interleave-division multiple-access systems, where the interleaver of each UE is available at the BS according to the one-to-one correspondence between UE's identity number (ID) and its interleaver [16]. However, since the grant-based random access schemes require two handshake processes between the base station (BS) and UEs, considering the small packet transmission in M2M communication, such kind of random access scheme will introduce heavy signaling overhead and low data transmission efficiency.

To address this problem, the grant-free random access schemes have attracted much attention in recent years, which allow active UEs to transmit their pilots and uplink messages to the BS directly and perform activity de-

tection, channel state information (CSI) estimation, and uplink message decoding in one shot. J. Ahn *et al.* proposed a Bayesian based random access scheme to detect the UE's activity and estimate the CSI jointly by utilizing the expectation propagation algorithm, considering the BS with one antenna [17]. L. Liu *et al.* proposed a approximate message passing (AMP) based grant-free scheme to achieve the joint activity detection and CSI estimation for massive MIMO systems [18]. However, this AMP-based grant-free random access scheme requires long pilot sequence to achieve better performance, resulting in heavy pilot overhead. To support massive connectivity with low access delay and overhead, a novel grant-free random access scheme was proposed to detect active UEs and uplink message without CSI estimation in one shot [19]. However, the CSI estimation is needed for some M2M traffics for downlink beamforming in the case of time-division duplex (TDD) model, such as the telemedicine surgery requiring the downlink control signal transmission. The above-mentioned grant-free random access schemes consider the single pilot structure. Jiang *et al.* proposed to concatenate multiple orthogonal sub-pilots into a super pilot sequence, and the super pilot sequence is utilized for activity detection and CSI estimation [20]. Simulation results show that, compared to the single pilot structure, this super pilot structure can improve the number of successful UEs by utilizing their proposed detection approach. However, with the increase of the number of active UEs, the probability that more UEs have the same super pilot sequence increases, resulting in low row rank pilot selection matrix and thus degrading the number of successful UEs. This motivates interesting researches on how to support massive access by utilizing the super pilot structure.

To achieve this goal, we propose a graph combined clustering independent component analysis based random access (GCICA-RA) scheme. This scheme utilizes the super pilot structure and mainly consists of two steps. During the first step, all the active UEs concatenate their randomly selected sub-pilots to obtain their super pilot sequences, and send their super pilot sequences and modulated uplink messages to the BS. During the second step, the BS performs CSI estimation and uplink message decoding jointly by utilizing a proposed GCICA decoding algorithm, employs the estimated CSIs to detect active UEs by utilizing the characteristic of asymptotic favorable propagation of massive MIMO channel, and sends random access response (RAR) to active UEs. We analyze the successful access probability, missed detection probability, and uplink throughput of the GCICA-RA scheme. Numerical results show that, compared to the random access scheme proposed in [20], the GCICA-RA scheme significantly improves the successful access probability and uplink throughput, decreases missed

detection probability, and provides low CSI estimation error at the same time.

The **main contributions** of this paper are summarized as follows.

- We propose a GCICA algorithm to perform CSIs estimation and uplink message decoding jointly. Specifically, based on the received sub-pilot signal, the BS first utilizes a successive interference cancellation (SIC) algorithm to estimate CSIs of active UEs, and then decodes the uplink message by utilizing the estimated CSIs. Then, the BS utilizes a proposed CICA algorithm to decode uplink message and estimate CSIs of UEs whose CSIs cannot be estimated by the SIC algorithm. Simulation results show that, compared to the detection method proposed in [20], the number of successful UEs can be improved even multiple UEs having the same super pilot sequence.
- For the SIC algorithm, we propose to employ the estimated CSIs without other overhead to find edges connecting to a recovered variable node, by utilizing the asymptotic favorable propagation of massive MIMO systems. This is different from the existing method where indexes of selected pilots should be inserted into the uplink message to find edges connected to a recovered variable node [14], which degrades data transmission efficiency.
- We analyze the upper bound for the successful access probability and uplink throughput of the proposed GCICA-RA scheme, and derive the lower bound for the missed detection probability of the proposed GCICA-RA scheme.

The remainder of this paper is organized as follows. Section II introduces system model and the proposed GCICA-RA scheme. Section III describes SIC and CICA algorithms in the the proposed GCICA-RA scheme. We present the performance analysis in Section IV. Simulation results and the conclusion are given in Section V and VI, respectively.

Notations utilized throughout this paper are described in Table I.

II. SYSTEM MODEL AND THE PROPOSED GCICA-RA SCHEME

A. SYSTEM MODEL

In this paper, we consider massive MIMO communication systems in time-division duplex (TDD) mode. There is a BS with M antennas and K single-antenna UEs in a cell, where the number of active UEs in a random access procedure is N_a.

In the proposed GCICA-RA scheme, each UE transmits its modulated uplink message and super pilot to the BS directly. The BS performs CSI estimation and

Notations	Description
Italic letters	Scalars
Boldface lower-case	Vectors
Boldface upper-case letters	Matrices
$(\cdot)^T$ and $(\cdot)^H$	The transpose and conjugate transpose of a vector or a matrix
'*'	Complex conjugate of a vector or a matrix
$\boldsymbol{x}_i$	The ith element of a vector $\boldsymbol{x}$
$\mathbb{R}$	The set of all real numbers
$\mathcal{CN}(\mu, \sigma^2)$	A circularly-symmetric complex Gaussian distribution with mean μ and variance σ^2
$\|\cdot\|$	The Euclidean norm of a vector
$\|\cdot\|$	The cardinality of a set
$\arg(d)$	The phase of complex d
$\lfloor \cdot \rceil$	The rounding operation
$[\boldsymbol{x}]_n$	The nth element of vector $\boldsymbol{x}$
$\boldsymbol{X}(i)$	The ith column of matrix $\boldsymbol{X}$

uplink message decoding by utilizing a proposed GCICA decoding algorithm, and then employs the estimated CSIs to detect active UEs. The frame structure of the GCICA-RA scheme is shown in Fig. 1. Specifically, the super pilot of each UE consists of L consecutive sub-pilots, and the symbol length of each sub-pilot is τ_p. Therefore, the symbol length of each super pilot is $L\tau_p$. In addition, the proposed GCICA decoding algorithm utilizes multiple ICA classifiers to separate source signals. However, the phase of the separated signals is unpredictable.

To solve this problem, each active UE inserts a reference symbol (termed RS) with symbol length 1 into its uplink message [19]. Let $\boldsymbol{v_k} = [v_k(1), v_k(2), \ldots, v_k(N_m)]^T$ denote the modulated uplink message of UE k, where N_m represents the symbol length of the modulated uplink message. Then, $v_k(1)$, $[v_k(2), \ldots, v_k(N_m)]$ represent the RS and the payload data with symbol length N_{PD}, respectively. Furthermore, since any complex symbol can be represented as a real symbol [21], we employ the BPSK modulation scheme in the proposed GCICA-RA scheme, i.e. $v_k(i) = \{\pm 1\}$.

Fig. 1. The frame structure of the proposed GCICA-RA scheme.

B. GCICA-RA scheme description

As shown in Fig. 2, the proposed GCICA-RA scheme allows each UE to transmit its modulated uplink message and super pilot to the BS directly. Then, the BS performs CSI estimation and uplink message decoding by utilizing a proposed GCICA decoding algorithm, employs the

estimated CSIs to detect active UEs, and sends RAR information to active UEs. In addition, the proposed GCICA decoding algorithm first utilizes a SIC algorithm to estimate CSIs and decode the uplink message of active UEs, performs the number of active UEs estimation, and utilizes a proposed CICA algorithm to decode uplink messages and estimate CSIs of active UEs whose CSIs cannot be recovered by the SIC algorithm. The details are described as follows.

1) Step 1: Super pilot and modulated uplink message transmission:

There are L sub-pilot phases, and each active UE randomly selects its sub-pilot from a set of mutually orthogonal normalized pilots $\boldsymbol{P_o} = \{\boldsymbol{S_1}, \boldsymbol{S_2}, \cdots, \boldsymbol{S_{\tau_p}}\} \in \mathbb{R}^{\tau_p \times \tau_p}$ during each sub-pilot phase. Concatenating these randomly selected sub-pilot sequences, each active UE obtains its super pilot. Following the frame structure as shown in Fig. 1, each active UE sends it super pilot and modulated uplink message to the BS. In addition, the value of RS is the same for all active UEs, and we set the RS to be 1, i.e., $v_k(1) = 1 \ \forall k$.

Then, let $\boldsymbol{g_k} = (g_k^1, g_k^2, \cdots, g_k^M)^T$ denote the independent and identically distributed (i.i.d.) small-scale fading channel from UE k to the BS, i.e., $\boldsymbol{g_k} \sim \mathcal{N}(0, \boldsymbol{I_M})$. Let ρ_k denote UE k's transmitting power. Let β_k stand for the channel gain between UE k and the BS, which can be known for UE k before the random access procedure [13]. Then, the received sub-pilot signal during the lth $(l = 1, 2, \ldots, L)$ sub-pilot phase at the BS is

$$\boldsymbol{Y}_p^l = \sum_{t=1}^{\tau_p} \sum_{k \in \boldsymbol{A_t^l}} \sqrt{\beta_k \rho_k} \boldsymbol{g_k}(\boldsymbol{S_t})^T + \boldsymbol{Z}_p^l, \ l = 1, 2, \ldots, L,$$ (1)

where $\boldsymbol{A_t^l}$ stands for the set of UEs that select pilot S_t during the lth sub-pilot phase, $\boldsymbol{Z}_p^l \in \mathbb{R}^{M \times \tau_p}$ denotes the additive white noise matrix with each element following from a distribution of $\mathcal{N}(0, \sigma^2)$. In this paper, $\boldsymbol{Z}$ with different subscripts or superscripts will follow the same distribution. In addition, we consider $\rho_k \beta_k = 1$ to make the received signal from all active UEs have the same power [22].

The received superimposed uplink message $\boldsymbol{Y}_m \in \mathbb{R}^{M \times N_m}$ at the BS is

$$\boldsymbol{Y}_m = \sum_{k=1}^{N_a} \boldsymbol{g_k}(\boldsymbol{v_k})^T + \boldsymbol{Z}_m.$$ (2)

2) CSI estimation, uplink message decoding, active UE detection and RAR transmission:

Based on the received sub-pilot signal and the superimposed uplink message, the BS performs ① CSI estimation and uplink message decoding jointly, and ② active UE detection and RAR information transmission. The details are described as follows.
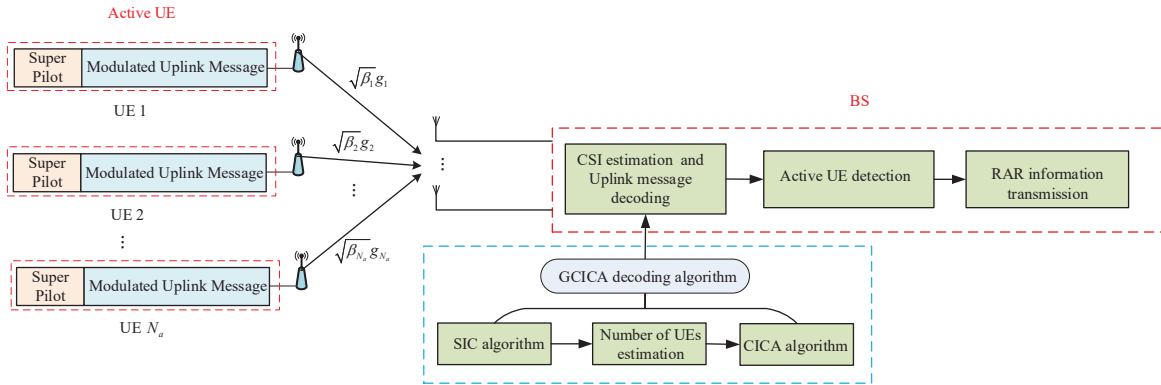

Fig. 2. Block diagram of the proposed GCICA-RA scheme. Each active UE sends its super pilot and modulated uplink message to the BS. The BS performs CSI estimation and uplink message decoding by utilizing a proposed GCICA decoding algorithm, employs the estimated CSIs to detect active UEs, and sends RAR information to active UEs. In addition, the proposed GCICA decoding algorithm utilizes a SIC algorithm to estimate CSIs and thus decodes the uplink message of active UEs, performs the number of active UEs estimation, and utilizes a proposed CICA algorithm to decode uplink message and estimate CSIs of active UEs whose CSIs cannot be recovered by the SIC algorithm.

① CSI estimation and uplink message decoding

The BS utilizes the proposed GCICA decoding algorithm to perform CSI estimation and uplink message decoding. The details of the GCICA decoding algorithm are described as follows.

The BS first estimates the CSI corresponding to pilot S_t during the lth sub-pilot phase by utilizing least squares (LS) method, denoted by h_t^l

$$h_t^l = Y_p^l(S_t)^* = \sum_{k \in A_t^l} g_k + Z_t^l. \quad (3)$$

It can be seen from (3) that, during the lth sub-pilot phase, the estimated CSI corresponding to pilot S_t is the sum of CSIs of active UEs selecting pilot S_t. So, considering all L sub-pilot phases, a bipartite graph can be used to describe the proposed GCICA-RA scheme, and thus the SIC algorithm can be utilized to estimate UEs' CSIs on the bipartite graph. The procedure of the SIC algorithm is described in Section III-A in detail. We use $\hat{H}_{\text{SIC}} = [\hat{h}_{\text{SIC}}^1, \cdots, \hat{h}_{\text{SIC}}^{N_{\text{SIC}}^s}] \in \mathbb{R}^{M \times N_{\text{SIC}}^s}$ to denote the estimated CSIs via the SIC algorithm, where N_{SIC}^s is the number of estimated CSIs via the SIC algorithm. Thus, the detected uplink message can be obtained by utilizing LS method

$$\hat{x}_{\text{SIC}}^i = \frac{(\hat{h}_{\text{SIC}}^i)^H Y_m}{(\hat{h}_{\text{SIC}}^i)^H (\hat{h}_{\text{SIC}}^i)}, 1 \le i \le N_{\text{SIC}}^s. \quad (4)$$

After demodulating and decoding the detected uplink message $\hat{x}_{\text{SIC}}^i$, we obtain the corresponding decoded uplink message $\hat{v}_{\text{SIC}}^i$.

Then, based on the estimated CSIs corresponding to all pilots during the lth sub-pilot phase, the BS estimates the number of active UEs by utilizing the estimation

method proposed in [19], denoted by $\hat{N}_a$, which is given by

$$\hat{N}_a = \sum_{t=1}^{\tau_p} \frac{(h_t^l)^H h_t^l}{M} \to \sum_{t=1}^{\tau_p} |A_t^l| = N_a, M \to \infty. \quad (5)$$

We can observe from (5) that $\hat{N}_a$ approaches N_a with large M. Therefore, the estimated number of active UEs whose CSIs cannot be obtained via the SIC algorithm is

$$\hat{N}_r = \hat{N}_a - N_{\text{SIC}}^s. \quad (6)$$

Finally, by utilizing $\hat{N}_r$, $\hat{v}_{\text{SIC}}^i (1 \le i \le N_{\text{SIC}}^s)$, and Y_m, the BS employs a proposed CICA algorithm to obtain the CSIs and decoded uplink message of active UEs whose CSIs cannot be obtained via the SIC algorithm, denoted by $\hat{H}_{\text{CICA}} = [\hat{h}_{\text{CICA}}^1, \cdots, \hat{h}_{\text{CICA}}^{\hat{N}_r}] \in \mathbb{R}^{M \times \hat{N}_r}$ and $\hat{v}_{\text{CICA}}^i$, respectively. The details of the CICA algorithm are descried in Section III-B.

② Active UE detection and RAR information transmission

The BS detects an active UE by judging whether its CSI can be estimated (i.e., whether the corresponding estimated CSI is a valid CSI estimation), and this UE realizes whether it has been detected by the BS in a distributed manner. The details are described as follows.

We utilize $\hat{H} = [\hat{H}_{\text{SIC}}, \hat{H}_{\text{CICA}}]$ to denote the estimated CSIs, and assume that $\hat{H}(1)$ is a valid CSI estimation. More specifically, $\hat{H}(1)$ is the estimated CSI for UE m (i.e., $\hat{H}(1) = g_m + \Delta g_m$, where Δg_m denotes the estimation error and takes small values). By correlating $\hat{H}(1)$ with the estimated CSI corresponding to pilot S_t during the lth sub-pilot phase (i.e., h_t^l, $t =$

$1, 2, \ldots, \tau_p$), we have

$$
\begin{aligned}
\frac{(\boldsymbol{h_t^l})^H \hat{\boldsymbol{H}}(1)}{M} &= \frac{\left(\sum\limits_{k \in \boldsymbol{A_t^l}} \boldsymbol{g_k} + \boldsymbol{Z_t^l}\right)^H (\boldsymbol{g_m} + \boldsymbol{\Delta g_m})}{M} \\
&= \frac{(\boldsymbol{g_m})^H \boldsymbol{g_m}}{M} + \frac{\sum\limits_{k \in \boldsymbol{A_t^l}, k \neq m} (\boldsymbol{g_k})^H \boldsymbol{g_m}}{M} + \\
&\quad \frac{\sum\limits_{k \in \boldsymbol{A_t^l}} (\boldsymbol{g_k})^H \boldsymbol{\Delta g_m}}{M} + \frac{(\boldsymbol{Z_t^l})^H (\boldsymbol{g_m} + \boldsymbol{\Delta g_m})}{M} \\
&\xrightarrow{(a)} 1, M \to \infty, \text{if } t \text{ is the index of}
\end{aligned}
$$

the pilot selected by UE m

$$
\begin{aligned}
\frac{(\boldsymbol{h_t^l})^H \hat{\boldsymbol{H}}(1)}{M} &= \frac{\sum\limits_{k \in \boldsymbol{A_t^l}} (\boldsymbol{g_k})^H \hat{\boldsymbol{H}}(1) + (\boldsymbol{Z_t^l})^H \hat{\boldsymbol{H}}(1)}{M} \\
&\xrightarrow{(b)} 0, M \to \infty, \text{otherwise}
\end{aligned}
$$

$$(7)$$

where (a) follows from the fact that, when M goes into infinity, terms $\frac{(\boldsymbol{g_m})^H \boldsymbol{g_m}}{M} = 1$, $\frac{\sum_{k \in \boldsymbol{A_t^l}, k \neq m} \boldsymbol{g_k}^H \boldsymbol{g_m}}{M} = 0$, $\frac{(\boldsymbol{Z_t^l})^H (\boldsymbol{g_m} + \boldsymbol{\Delta g_m})}{M} = 0$ by utilizing the asymptotic favorable propagation of massive MIMO channel, term $\frac{\sum_{k \in \boldsymbol{A_t^l}} (\boldsymbol{g_k})^H \boldsymbol{\Delta g_m}}{M}$ is close to 0 since elements in $\boldsymbol{\Delta g_m}$ are small values, and (b) is derived based on the random matrix theory. In addition, it is easy to derive that, when $\hat{\boldsymbol{H}}(i)$ is not a valid CSI estimation, $\frac{(\boldsymbol{h_t^l})^H \hat{\boldsymbol{H}}(i)}{M}$ is close to 0 by utilizing the random matrix theory. Therefore, the BS utilizes the following rule to judge whether $\hat{\boldsymbol{H}}(i)$ is a valid CSI estimation: for the lth ($l \in \{1, ..., L\}$) sub-pilot phase, if there only exits an element in set $[\frac{(\boldsymbol{h_l^1})^H \hat{\boldsymbol{H}}(i)}{M}, \cdots, \frac{(\boldsymbol{h_l^t})^H \hat{\boldsymbol{H}}(i)}{M}, \cdots, \frac{(\boldsymbol{h_l^{\tau_p}})^H \hat{\boldsymbol{H}}(i)}{M}]$ close to 1, $\hat{\boldsymbol{H}}(i)$ is a valid CSI estimation because each active UE only selects one pilot during each sub-pilot phase; otherwise, $\hat{\boldsymbol{H}}(i)$ is not a valid CSI estimation.

After obtaining all valid CSIs, the BS generates and broadcasts the RAR information $\boldsymbol{V} = \sum_{u \in \boldsymbol{B}} (\hat{\boldsymbol{H}}(u))^H$ to all active UEs where $\boldsymbol{B}$ stands for the index set of valid CSI estimations.

The received RAR at UE m is

$$
R_m = \sqrt{\beta_m} \boldsymbol{V} \boldsymbol{g_m} + Z_d. \tag{8}
$$

Then, we have

$$
\begin{aligned}
\frac{R_m}{\sqrt{\beta_m} M} &= \frac{\sqrt{\beta_m} \boldsymbol{V} \boldsymbol{g_m}}{\sqrt{\beta_m} M} + \frac{Z_d}{\sqrt{\beta_m} M} \\
&= \frac{\sqrt{\beta_m} \left(\sum\limits_{u \in \boldsymbol{B}} (\hat{\boldsymbol{H}}(u))^H \boldsymbol{g_m}\right)}{\sqrt{\beta_m} M} + \frac{Z_d}{\sqrt{\beta_m} M} \\
&\xrightarrow{(a) M \to \infty} \begin{cases} 1 & \text{if UE } m \text{ has been detected} \\ 0 & \text{otherwise} \end{cases}
\end{aligned}
$$

$$(9)$$

where (a) is derived by utilizing the asymptotic favorable propagation of massive MIMO channel, similar to (7). Based on the value of $\frac{R_m}{\sqrt{\beta_m} M}$, UE m can realize whether it has been detected. If not, UE m will reattempt the random access procedure in the upcoming random access slot.

III. SIC AND CICA ALGORITHMS

A. SIC Algorithm

As we described in Section II-B, a bipartite graph can be used to describe the proposed GCICA-RA scheme, and thus the SIC algorithm can be utilized to estimate UEs' CSIs on the bipartite graph. In this subsection, we first present the bipartite graph representation, and then describe the SIC algorithm in detail.

1) Bipartite Graph Representation:

A bipartite graph consists of variable nodes, factor nodes, and edges connecting variable nodes and factor nodes. We utilize active UEs and available pilots during each sub-pilot phase to represent variable nodes and factor nodes, respectively. Furthermore, if pilot $\boldsymbol{S_t}$ is selected by UE k during sub-pilot phase l, we use t^l to denote the corresponding factor node, and there exists an edge connecting the variable node k with the factor node t^l. The CSI of UE k is marked on edges connected to UE k. Note that, since we use the power control mechanism to make $\rho_k \beta_k = 1$, we only need to estimate the small-scale fading channel. So, we only mark the small-scale fading coefficients between the BS and active UE. Furthermore, the degree of a node is referred to the number of edges connected to this node.

Example: Fig. 3(a) illustrates a bipartite graph based on 5 active UEs, 2 sub-pilot phases, and 3 available pilots. During each sub-pilot phase, active UEs (represented by circles) are variable nodes and all available pilots (represented by squares) are factor nodes. Since UE 1 and UE 2 select pilot $\boldsymbol{S_1}$ during sub-pilot phase 1, UE 1 and UE 2 are connected to factor node 1^1 by a black solid line. Since UE 3 selects pilot $\boldsymbol{S_2}$ during sub-pilot phase 1, UE 3 is connected to factor node 2^1 by a black solid line. Since UE 4 and UE 5 select pilot $\boldsymbol{S_3}$ during sub-pilot phase 1, UE 4 and UE 5 are connected to factor node 3^1 by a black solid line. Since UE 1 and UE 3 select pilot $\boldsymbol{S_1}$ during sub-pilot phase 2, UE 1 and UE 3 are connected to factor node 1^2 by a black solid line. Since UE 2, UE 4, and UE 5 all select pilot $\boldsymbol{S_3}$ during sub-pilot phase 2, UE 2, UE 4 and UE 5 are connected to factor node 3^2 by a black solid line.

2) SIC Algorithm:

The BS employs SIC algorithm to estimate UE's CSI on the bipartite graph, and then utilizes the estimated CSIs to decode the uplink message. In the following,
Fig. 3. An example of SIC process.

we briefly discuss the SIC algorithm, present the pseudo-code of the SIC algorithm in Algorithm 1, and give an example to show the SIC algorithm intuitively.

By performing the autocorrelation operation on CSI corresponding to each pilot during each sub-pilot phase, we have

$$\frac{(h_t^l)^H h_t^l}{M} = \frac{\sum_{k \in A_t^l} (g_k)^H g_k + \left(\sum_{k \in A_t^l} g_k + Z_t^l\right)^H Z_t^l}{M}$$
$$\xrightarrow{(a)} |A_t^l|, M \to \infty, \tag{10}$$

where (a) can be easily derived by utilizing the characteristic of asymptotic favorable propagation of massive MIMO channel.

(10) shows that, with large M, $\frac{(h_t^l)^H h_t^l}{M}$ approaches the number of active UEs selecting pilot S_t during the lth sub-pilot phase. In other words, $\frac{(h_t^l)^H h_t^l}{M}$ represents the degree of factor node t^l.

During the first SIC iteration, the BS first finds factor nodes with degree 1 by utilizing (10). A factor node with

degree 1 indicates that there is only one UE selecting the corresponding sub-pilot and the corresponding CSI can be recovered. Then, the BS finds other selected sub-pilots of UEs whose CSIs are recovered. More specifically, for each CSI corresponding to factor node with degree larger than 1, after subtracting each recovered CSI, the BS utilizes (10) to compute the new degree of this factor node. If the new degree is less than the previous degree, this means that the sub-pilot corresponding to this factor node is selected by active UE corresponding to this recovered CSI. We subtract the recovered CSI from the CSI corresponding to this factor node and update the new degree as the previous degree of this factor node. This is equivalent to delete the edges between this active UE and its selected sub-pilots on the bipartite graph. Thus, a new bipartite graph can be obtained, and SIC iteration continues until there is no factor node with degree 1.

Since each active UE selects its sub-pilots randomly, there exits the case of UE k having no pilot collision during multiple sub-pilot phases. This results in the case of the recovered multiple CSIs corresponding to the same UE. Luckily, by utilizing the asymptotic favorable propagation of massive MIMO channel, we can find these CSIs from the recovered CSIs and select one of them as the recovered CSI of this UE. For example, if estimated $\hat{h}_1$ and $\hat{h}_2$ correspond to the same active UE, by utilizing the asymptotic favorable propagation of massive MIMO channel, $\frac{(\hat{h}_1)^H \hat{h}_2}{M}$ is close to 1 with large M. Otherwise, $\frac{(\hat{h}_1)^H \hat{h}_2}{M}$ is close to 0 with large M. Finally, the recovered CSIs via the SIC algorithm are $\hat{H}_{\text{SIC}} = [\hat{h}_{\text{SIC}}^1, \cdots, \hat{h}_{\text{SIC}}^{N_{\text{SIC}}^s}] \in \mathbb{R}^{M \times N_{\text{SIC}}^s}$.

Algorithm 1 gives the detailed iteration process of SIC algorithm, where $h_{i,j}^k$ to represent the CSI corresponding to factor node j^k during the ith iteration.

To better understand the SIC algorithm, an example is given to illustrate the SIC algorithm. The details are described as follows:

During the first iteration (Fig. 3(a)), the BS finds that the degree of factor node 2^1 is 1 based on (10). So the BS can directly recover the CSI of UE 3, and incorporates this CSI (i.e., $h_{1,2}^1$) into the set $\hat{H}_{\text{SIC}}$. Then, after subtracting h_{SIC}^1 from CSIs corresponding to factor node with degree larger than 1, the BS finds that the new degree of factor node 1^2 is less than the previous degree according to (10), and thus realizes that the other index of sub-pilot selected by this UE is 1 in the second sub-pilot phase. Subtracting the recovered CSI from the CSI corresponding to factor node 1^2 (i.e, deleting the lines connected to variable node UE 3), a new bipartite graph can be obtained. Same as above operation, the BS can recover the CSI of UE 1 during the second iteration (i.e., $h_{2,1}^2$ Fig.3(b)) and the CSI of UE 2 during the third iteration (i.e., $h_{3,1}^1$ Fig.3(c)). In the end, since there

Algorithm 2: CICA decoding algorithm

Input : $Y_{\text{m}}' = [Y_{\text{m}}(1), Y_{\text{m}}(2), \cdots, Y_{\text{m}}(M)]^T$, $\hat{N}_r$
Output: $\hat{v}_{\text{CICA}}$: a set of decoded uplink message, $\hat{H}_{\text{CICA}}$: a set of estimated CSIs;
1 $r = N_{\text{I}}, \hat{v}_{\text{CICA}} = \phi, \hat{H}_{\text{CICA}} = \phi$;
2 **while** $(r \neq 0)$ **do**
3   $f_i \leftarrow$ Select $\hat{N}_r$ row vectors from Y_m' randomly to obtain Y_{ICA}^i, and then feed it to the ith ICA classifier to obtain separated source signal $f_i = [f_i^1, f_i^2, ..., f_i^{N_r}]$;
4   $r = r - 1$;
5 **end**
6 **for** *all* $i \in \{1, 2, ..., N_I\}, t \in \{1, 2, ..., \hat{N}_r\}$ **do**
7   $\hat{f}_i^t \leftarrow$ Use the first decoding symbol in f_i^t to solve the ICA phase ambiguity problem via (12);
8   $\text{DEC}(\hat{f}_i^t) \leftarrow$ After the first symbol in $\hat{f}_i^t$ is deleted, $\hat{f}_i^t$ is fed into the decoder to obtain the decoded signal $\text{DEC}(\hat{f}_i^t)$;
9   $j \leftarrow$ Judge which class $\text{DEC}(\hat{f}_i^t)$ belongs to by using the proposed clustering algorithm (assume it belongs to class j) ;
10   $C_j \leftarrow$ Incorporate this signal to the decoded signal set of the corresponding class ;
11   $\hat{d}_j \leftarrow$ Add the remodulated signal via (13);
12 **end**
13 **for** $j \in \{1, 2, ..., \hat{N}_r\}$ **do**
14   $\hat{v}_{\text{CICA}}^j = \text{sign}(\hat{d}_j), \hat{v}_{\text{CICA}} = \hat{v}_{\text{CICA}} \cup \hat{v}_{\text{CICA}}^j$;
15   $\hat{h}_{\text{CICA}}^j = \frac{Y_m'(\hat{v}_{\text{CICA}}^j)^*}{(\hat{v}_{\text{CICA}}^j)^H (\hat{v}_{\text{CICA}}^j)}$;
16   $\hat{H}_{\text{CICA}} = \hat{H}_{\text{CICA}} \cup \hat{h}_{\text{CICA}}^j$;
17 **end**
Return: $\hat{v}_{\text{CICA}} = [\hat{v}_{\text{CICA}}^1, \hat{v}_{\text{CICA}}^2, \cdots, \hat{v}_{\text{CICA}}^{\hat{N}_r}]$; $\hat{H}_{\text{CICA}} = [\hat{h}_{\text{CICA}}^1, \cdots, \hat{h}_{\text{CICA}}^{\hat{N}_r}]$.

is no factor node with degree 1 (Fig.3(d)), SIC ends. Finally, by utilizing the asymptotic favorable propagation of massive MIMO channel, we find that the recovered CSIs (i.e., $h_{1,2}^1$, $h_{2,1}^2$, and $h_{3,1}^1$) belong to different UEs. Hence, we have $\hat{h}_{\text{SIC}}^1 = h_{1,2}^1$, $\hat{h}_{\text{SIC}}^2 = h_{2,1}^2$, and $\hat{h}_{\text{SIC}}^3 = h_{3,1}^1$.

B. CICA algorithm

We can see from Fig. 3 that, for these 5 active UEs, we can only recover CSIs of UE 1, UE 2, and UE 3 by utilizing the SIC algorithm, and UE 4 and UE 5 fail to access the network. We propose a CICA algorithm to further obtain the CSIs and decoded uplink messages of UE 4 and UE 5. We briefly describe the CICA algorithm in Algorithm 2. In the following, we use the term "the remaining active UEs" to represent active UEs whose

CSIs cannot be recovered by the SIC algorithm for simplify representation. The proposed CICA algorithm first ① utilizes multiple ICA classifiers to separate the source signals and obtain the decoded signals, and then ② employs a proposed clustering algorithm to obtain estimated CSIs and decoded uplink messages of the remaining active UEs. The details are described as follows.

① **ICA classifiers**

The BS first obtains the sum of received superimposed uplink message of the remaining active UEs, denoted by

$Y_{\mathrm{m}}^{'} \in \mathbb{R}^{M \times N_{\mathrm{m}}}$.

$$Y_{\mathrm{m}}^{'} = Y_{\mathrm{m}} - \sum_{i=1}^{N_{\mathrm{SIC}}^{\mathrm{s}}} h_{\mathrm{SIC}}^{i}(\hat{v}_{\mathrm{SIC}}^{i})^{T}$$
$$= \sum_{i=1}^{N_{\mathrm{r}}} g_i(v_i)^{\mathrm{T}} + Z_{\mathrm{m}}^{'} \qquad (11)$$
$$= G_{\mathrm{r}}V_{\mathrm{r}} + Z_{\mathrm{m}}^{'}.$$

where N_{r} denotes the number of the remaining active UEs. Recall that we can obtain the estimated value of N_{r} (i,e., $\hat{N}_{\mathrm{r}}$) by utilizing (6).

Then, by utilizing the ICA method in [19], the BS utilizes N_{I} ICA classifiers to separate the source signals V_{r} in $Y_{\mathrm{m}}^{'}$. More specifically, the BS randomly selects $\hat{N}_{\mathrm{r}}$ different row vectors from $Y_{\mathrm{m}}^{'} = [Y_{\mathrm{m}}^{'}(1), \cdots, Y_{\mathrm{m}}^{'}(M)]^{T}$ as the input signal of the ith ICA classifier, and the ith ICA classifier outputs the separated source signal, denoted by $f_i = [f_i^1, \cdots, f_i^{\hat{N}_{\mathrm{r}}}]$, $i = 1, \ldots, N_{\mathrm{I}}$. We further use the first symbol in each separated source signal to solve the phase ambiguity problem introduced by the ICA classifier as follows

$$\hat{f}_i^t = f_i^1(t) \times f_i^t, (i \in \{1, 2, ..., N_{\mathrm{I}}\}, t \in \{1, 2, ..., \hat{N}_{\mathrm{r}}\}). \qquad (12)$$

Finally, after deleting the first symbol in $\hat{f}_i^t$, $\hat{f}_i^t$ is fed into the channel decoder to obtain the decoded signal $\mathrm{DEC}(\hat{f}_i^t)$. Thus, we can obtain the decoded signal from the ith ICA classifier, i.e., $\mathrm{DEC}(f_i) = [\mathrm{DEC}(f_i^1), \cdots, \mathrm{DEC}(f_i^t), \cdots, \mathrm{DEC}(f_i^{\hat{N}_{\mathrm{r}}})]$.

② **Clustering algorithm**

The order of the ICA classifier output is undetermined, and thus we cannot sure which UE each decoded signal from the ith ICA classifier belongs to. To solve this problem, we propose a clustering algorithm to cluster the decoded signals of the same UE from these N_{I} ICA classifiers, and further obtain the estimated CSIs and decoded uplink messages of the remaining active UEs.

We regard each remaining active UE as a class, and the decoded signals of one UE belong to the same class. Therefore, there are $\hat{N}_{\mathrm{r}}$ classes, indexed by $1, 2, \ldots, \hat{N}_{\mathrm{r}}$. Actually, since each ICA classifier outputs decoded signals of $\hat{N}_{\mathrm{r}}$ UEs, we can utilize decoded signals from any ICA classifiers as the first sample in each class. Here, we assume that $\hat{N}_{\mathrm{r}}$ decoded signals from the first ICA classifier (i.e., $\mathrm{DEC}(f_1)$) are the first sample in each class accordingly.

The BS first judges which class each decoded signal from the ith ($i = 2, \ldots, \hat{N}_{\mathrm{I}}$) ICA classifier belongs to. More specifically, considering that the fewer the number of different bits between two decoded signals, the more likely these two decoded signals come from the same UE. The BS compares the number of different bits between the decoded signal $\mathrm{DEC}(f_i^t)$, ($t = 1, 2, \ldots, \hat{N}_{\mathrm{r}}$) and each element in $\mathrm{DEC}(f_1)$, and judges $\mathrm{DEC}(f_i^t)$ belonging to the class which has the minimum number

of different bits with $\mathrm{DEC}(f_i^t)$. We use C_j to denote a set of decoded signals in the jth class.

Then, for the jth class, the BS remodulates each element in set C_j by utilizing the BPSK modulator and performs the sum operation as follows

$$\hat{d}_j = \sum_{i=1}^{|C_j|} 2 \times C_j(i) - 1, \qquad (13)$$

where $2 \times C_j(i) - 1$ refers to the remodulated signal.

Finally, the decoded uplink message of the remaining active UE can be obtained by

$$\hat{v}_{\mathrm{CICA}}^j = \mathrm{sign}(\hat{d}_j), \ j = 1, \ldots, \hat{N}_{\mathrm{r}}, \qquad (14)$$

and the estimated CSIs of the remaining active UEs can be obtained by

$$\hat{h}_{\mathrm{CICA}}^j = \frac{Y_{\mathrm{m}}^{'}(\hat{v}_{\mathrm{CICA}}^j)^{*}}{(\hat{v}_{\mathrm{CICA}}^j)^{H}(\hat{v}_{\mathrm{CICA}}^j)}, \ j = 1, \ldots, \hat{N}_{\mathrm{r}}. \qquad (15)$$

IV. PERFORMANCE ANALYSIS

In this section, we analyze the performance of the proposed GCICA-RA scheme, including the successful access probability, missed detection probability, and the uplink throughput.

A. Successful access probability analysis

Based on the procedure of the proposed GCICA-RA scheme, if the CSI of one UE can be obtained, this UE is a detected UE and its uplink message can also be decoded. This means that this UE can access the network successfully. The GCICA-RA scheme first utilizes the SIC algorithm to obtain the CSIs of active UEs, and then employs the proposed CICA algorithm to obtain the CSIs of active UEs whose CSI cannot be recovered by the SIC algorithm. Let $S_{\mathrm{GCICA\text{-}RA}}$, S_{SIC} and S_{CICA} denote the number of successful UEs obtained by the proposed GCICA-RA scheme, the SIC algorithm and the CICA algorithm, respectively. Then, the successful access probability of the proposed GCICA-RA scheme is given by

$$P_s = \frac{S_{\mathrm{GCICA\text{-}RA}}}{N_a} = \frac{S_{\mathrm{SIC}} + S_{\mathrm{CICA}}}{N_a}. \qquad (16)$$

Next, we discuss how to compute terms S_{SIC} and S_{CICA} in (16).

1) S_{SIC} computation :

To compute S_{SIC}, we follow the two assumptions below [14]:

Assumption 1: If an active UE has no pilot collision with other active UEs, its CSI can be recovered successfully.

Assumption 2: When an active UE selects the same pilot with other l active UEs, if CSIs of these l UEs can be recovered, its CSI can be recovered successfully.

Let P_{fail} denote the probability that UE's CSI cannot be recovered by the SIC algorithm. Then, we have

$$S_{\text{SIC}} = N_a \left(1 - P_{\text{fail}}\right). \tag{17}$$

The and-or tree principle is used to study random process, and we employ this principle to compute P_{fail}. In the following, we first derive the degree distributions of the proposed GCICA-RA scheme, and then discuss how to utilize the and-or tree principle to compute P_{fail} based on the derived degree distributions.

① **Degree distributions of the proposed GCICA-RA scheme derivation**

Let Λ_l and Ψ_l denote the probability that the degree of a variable node is l and the probability that the degree of a factor node is l, respectively. Then, the corresponding polynomial representations are given by

$$\Lambda(x) \triangleq \sum_l \Lambda_l x^l, \quad \Psi(x) \triangleq \sum_l \Psi_l x^l. \tag{18}$$

The proposed GCICA-RA scheme allows each active UE to select its sub-pilot during each sub-pilot phase, and there are L sub-pilot phases. Therefore, the degree of each variable node is L, i.e.,

$$\Lambda_l = \begin{cases} 1, & l = L, \\ 0, & \text{otherwise.} \end{cases} \tag{19}$$

In addition, since each active UE randomly selects its sub-pilot during each sub-pilot phase, the event that l active UEs select the same sub-pilot follows a Bernoulli distribution with parameters N_a and $1/\tau_p$. Thus, the probability of a factor node with degree l (i.e., Ψ_l) is

$$\Psi_l = \binom{N_a}{l} \left(\frac{1}{\tau_p}\right)^l \left(1 - \frac{1}{\tau_p}\right)^{(N_a - l)}. \tag{20}$$

Let λ_l denote the probability of an edge connecting to a variable node with degree l, and ρ_l denote the probability of an edge connecting to a factor node with degree l. Then, we transfer the node-perspective presentations in (19) and (20) into the edge perspective presentations, respectively

$$\lambda_l = \frac{\Lambda_l l}{\sum_l \Lambda_l l}, \quad \rho_l = \frac{\Psi_l l}{\sum_l \Psi_l l}, \tag{21}$$

and the polynomial representations are

$$\lambda(x) \triangleq \sum_l \lambda_l x^{l-1}, \rho(x) \triangleq \sum \rho_l x^{l-1}. \tag{22}$$

② P_{fail} **computation**

Considering a factor node with degree l (i.e., there are l UEs selecting the corresponding pilot), an edge connecting to this factor node can be recovered when the other $l-1$ edges connecting to this factor node have been recovered, as shown in Fig. 4(a). Similarly, as shown in Fig. 4(b), considering a variable node with degree l (i.e., UE corresponding to this variable node sends l sub-pilots

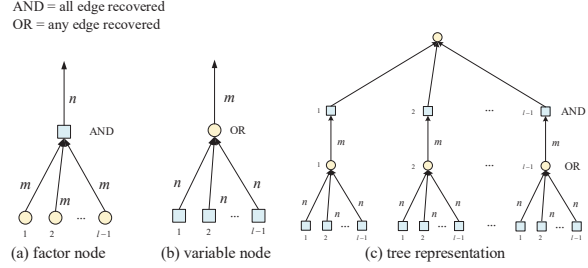

Fig. 4. Probability updates

to the BS), an edge connecting to a variable node with degree l can be recovered when at least one of the other $l-1$ edges have been recovered. Let $n(m)$ denote the probability that an edge connecting to a factor (variable) node with degree l cannot be recovered. Then, we have

$$n = 1 - (1 - m)^{l-1}, \tag{23}$$

and

$$m = n^{l-1}. \tag{24}$$

By averaging m and n over the edge distributions, the evolution of the average erasure probability during the ith $(1 \leq i \leq I)$ iteration where I is the maximum number of iterations, can be written as

$$\begin{aligned} n_i &= \sum_l \rho_l \left(1 - (1 - m_{i-1})^{l-1}\right) \\ &= 1 - \rho\left(1 - m_{i-1}\right), \end{aligned} \tag{25}$$

$$m_i = \sum_l \lambda_l n_i^{l-1} = \lambda\left(n_i\right).$$

The update process of m_i and n_i is shown in Fig. 4(c). Specifically, given initial values m_0 and n_0, m_i and n_i can be derived by (25).

It can be seen from Fig. 4(b) that, a variable node with degree l is unknown when all of these l edges cannot be recovered in the Ith iteration. So, the probability of the variable node being unknown is $(n_I)^l$. By averaging $(n_I)^l$ over the degree distributions of variable nodes, P_{fail} can be calculated by [23]

$$P_{\text{fail}} = \sum_l \Lambda_l (n_I)^l = \Lambda(n_I). \tag{26}$$

Substituting (26) into (17), we have

$$S_{\text{SIC}} = N_a \left(1 - P_{\text{fail}}\right) = N_a(1 - \Lambda(n_I)). \tag{27}$$

2) S_{CICA} *computation :*

The number of successful UEs obtained by the CICA algorithm can be written as

$$S_{\text{CICA}} = (N_a - S_{\text{SIC}})P_{\text{CICA}}^s, \tag{28}$$

where P_{CICA}^s denotes the probability that the CSI of one UE can be obtained successfully.

Based on the procedure of the CICA algorithm described in Subsection III-B, we can see that, the CICA algorithm first obtains the decoded uplink message via (14), and then obtains UE's CSI via (15). Thus, if the uplink message of one UE can be decoded successfully, the CSI of this UE can be recovered successfully. Then, P_{CICA}^s can be computed by

$$P_{\text{CICA}}^s = (1 - P_e)^{N_{\text{m}}}. \qquad (29)$$

where P_e is the bit error rate (BER) of the proposed CICA algorithm, which is larger than that using maximum likelihood (ML) decoding method [24], and can be written as

$$P_e \geq \frac{1}{\sqrt{\pi}} \int_{\sqrt{\rho_1 \beta_1 \sum_{m=1}^M (g_{1,m})^2}}^{\infty} e^{-x^2} dx$$

$$\overset{(a)}{=} \frac{1}{\sqrt{\pi}} \int_0^\infty \int_{\sqrt{y}}^\infty \frac{y^{M/2-1} e^{-y/2}}{2^{M/2} \Gamma(\frac{M}{2})} e^{-x^2} dx dy, \qquad (30)$$

where step (a) follows from the fact that $\sum_{m=1}^M (g_{1,m})^2$ is a central chi-squared distribution with degree of freedom M and that $\rho_1 \beta_1 = 1$, and $\Gamma(z)$ is the gamma function with parameter z which is given by

$$\Gamma(z) = \int_0^\infty t^{z-1} e^{-t} dt. \qquad (31)$$

Substituting (30) into (29), we can derive the upper bound for P_{CICA}^s,

$$P_{\text{CICA}}^s \leq P_{\text{CICA}}^{\text{U}} = \left(1 - \frac{1}{\sqrt{\pi}} \int_0^\infty \int_{\sqrt{y}}^\infty \frac{y^{M/2-1} e^{-y/2}}{2^{M/2} \Gamma(\frac{M}{2})} e^{-x^2} dx dy\right)^{N_{\text{m}}}, \qquad (32)$$

and thus derive the upper bound for S_{CICA}

$$\begin{aligned}
S_{\text{CICA}} &\leq S_{\text{CICA}}^{\text{U}} \\
&= P_{\text{CICA}}^{\text{U}}(N_a - S_{\text{SIC}}) \\
&= \left(1 - \frac{1}{\sqrt{\pi}} \int_0^\infty \int_{\sqrt{y}}^\infty \frac{y^{M/2-1} e^{-y/2}}{2^{M/2} \Gamma(\frac{M}{2})} e^{-x^2} dx dy\right)^{N_{\text{m}}} \\
&\quad \times (N_a - S_{\text{SIC}}). \qquad (33)
\end{aligned}$$

Substituting (33), (27) into (16), we can get the upper bound for the successful access probability of the proposed GCICA-RA scheme

$$\begin{aligned}
P_s \leq P_s^{\text{U}} = &\frac{(N_a \Lambda(n_I)) \left(1 - \frac{1}{\sqrt{\pi}} \int_0^\infty \int_{\sqrt{y}}^\infty \frac{y^{M/2-1} e^{-y/2}}{2^{M/2} \Gamma(\frac{M}{2})} e^{-x^2} dx dy\right)^{N_{\text{m}}}}{N_a} \\
&+ \frac{N_a(1 - \Lambda(n_I))}{N_a}. \qquad (34)
\end{aligned}$$

B. Missed detection probability analysis

The missed detection probability refers to the ratio of the number of undetected active UEs to the total number of active UEs, which can be calculated as

$$P_{\text{md}} = \frac{N_a - S_{\text{GCICA-RA}}}{N_a} = 1 - P_s. \qquad (35)$$

Substituting (34) into (35), we can get the lower bound for the missed detection probability

$$\begin{aligned}
P_{\text{md}} \geq \ &P_{\text{md}}^{\text{L}} \\
= \ &1 - P_s^{\text{U}} \\
= \ &1 - [\frac{N_a(1-\Lambda(n_I))}{N_a} + (N_a \Lambda(n_I)) \times \\
&\frac{\left(1 - \frac{1}{\sqrt{\pi}} \int_0^\infty \int_{\sqrt{y}}^\infty \frac{y^{M/2-1} e^{-y/2}}{2^{M/2} \Gamma(\frac{M}{2})} e^{-x^2} dx dy\right)^{N_{\text{m}}}}{N_a}].
\end{aligned}$$
$$(36)$$

C. Uplink throughput analysis

We define the uplink throughput as follows

$$\gamma = \frac{S_{\text{SchemeName}} N_{\text{PD}} R}{N_{\text{PD}} + O_{\text{SchemeName}}} = \frac{N_a P_s N_{\text{PD}} R}{N_{\text{PD}} + O_{\text{SchemeName}}}, \qquad (37)$$

where $S_{\text{SchemeName}}$ denotes the number of successful UEs where subscript "SchemeName" stands for the name of the scheme, $O_{\text{SchemeName}}$ denotes the overhead of the random access scheme, and $N_{\text{PD}} + O_{\text{SchemeName}}$ is the frame length. Fig. 1 indicates that the amount of total overhead of the proposed GCICA-RA scheme is $O_{\text{GCICA-RA}} = \tau_p \times L + 1$.

Substituting (34) into (37), we can derive the upper bound for the uplink throughput of the proposed GCICA-RA scheme

$$\gamma \leq \gamma^{\text{U}} = \frac{N_a P_s^{\text{U}} N_{\text{PD}} R}{N_{\text{PD}} + \tau_p \times L + 1}. \qquad (38)$$

V. NUMERICAL RESULTS

In this section, we first present the performance of the proposed GCICA-RA scheme, including the successful access probability, missed detection probability, and MSE performance of the CSI estimation method. Then, we make a comparison between the proposed GCICA-RA scheme, multiple-preamble grant-free RA scheme proposed in [20] and the traditional random access scheme in terms of the uplink throughput. For the traditional random access scheme, active UEs sends their randomly selected pilots along with their uplink messages to the BS, and the BS can only decode the uplink message of UE free from pilot collision.

In the simulation, we consider the urban micro scenario, where the path loss exponent is 3.8 [25]. The radius of the cell is 200 meters and all UEs are uniformly distributed among the location farther than 25 meters

from the BS. Simulation parameters are shown in Table
II. In addition, we utilize a LDPC code with 1/2 rate
to code the payload data, and then employ the BPSK
scheme to module the coded payload data. In the simu-
lation, since the length of payload data is a few hundred
bytes in M2M communications [26], the payload data
size is set to 128 bytes to meet the communication
requirements of M2M communications, and further to
verify the proposed GCICA-RA scheme.

TABLE II
SIMULATION PARAMETERS

| Parameter		Value
R (Code rate)		1/2
N_{PD}	(Symbol length of the coded payload data)	2048
M (The number of antennas)		400
SNR_e	(Median signal to noise ratio (SNR) of the UEs at the corner of cell)	5, 10, 15, 20 dB
τ_p (The number of pilots during each sub-pilot phase)		6,9,10
L (The number of sub-pilot phases)		2,3
N_{I} (The number of ICA classifiers)		5~30
N_a	(The number of active UEs during one random access procedure)	$10 \sim 40$
Fig. 5. Successful access probability versus the number of ICA classifiers N_{I}.

Fig. 6. Missed detection probability versus the number of ICA classifiers N_{I}.
Fig. 7. MSE performance versus the number of ICA classifiers N_{I}.

Fig. 5 shows how the successful access probability P_s
changes with the number of ICA classifiers N_{I}, where
$\text{SNR}_e = 5, 10, 15, 20$ dB, $M = 400$, $L = 2$, $N_a = 20$
and $\tau_p = 10$. The upper bound for the successful
access probability can be obtained according to (34).
We can see from Fig. 5 that, with the increase of N_{I},
the successful access probability increases dramatically
first and then increases at a slower pace for different
SNR_e. The reason is that, the more the number of ICA
classifiers, the more signals of one UE we can obtain,
which further improves the decoding performance. We
can also observe that, with the increase of SNR_e, the
successful access probability increases, and is close to
the upper bound.

Fig. 6 shows how the missed detection probability
changes with the number of ICA classifiers N_{I}, where
$\text{SNR}_e = 5, 10, 15, 20$ dB, $M = 400$, $L = 2$, $N_a = 20$
and $\tau_p = 10$. The lower bound for the missed detection
probability can be obtained according to (36). Fig. 6
illustrates that, with the increase of N_{I}, the missed
detection probability decreases dramatically first and
then decreases at a slower pace for different SNR_e. We
can also note that, with the increase of SNR_e, the missed
detection probability takes small values and decreases,
and is close to the lower bound.

Fig. 7 illustrates MSE performance of the proposed
GCICA-RA, where $\text{SNR}_e = 5, 10, 15, 20$ dB, $M = 400$,
$L = 2$, $N_a = 20$ and $\tau_p = 10$. We can see from
Fig. 7 that, with the increase of N_{I}, MSE decreases

Fig. 8. Uplink throughput comparison between GCICA-RA and multiple-preamble grant-free RA scheme.

dramatically first and then decreases at a slower pace for different SNR_e. We can also note that MSE takes small values and decreases with the increase of SNR_e.

Fig. 8 compares the uplink throughput between the proposed GCICA-RA, multiple-preamble grant-free RA schemes in [20], and the traditional random access scheme with different L. We set $M = 400$, $SNR_e = 10$ dB and $N_I = 30$. To see how the uplink throughput changes with the number of sub-pilot phases, we fix the length of the super pilot to 18, i.e., $L \times \tau_p = 18$, and set L to 2 and 3. To compare fairly, we ensure all random access scheme have the same pilot length and the same symbol length of the modulated uplink message. The upper bound for the uplink throughput of the proposed GCICA-RA is obtained via (38). Note that, since upper bounds for the uplink throughput of the proposed GCICA-RA are same for cases of $L = 2$ and $L = 3$ based on (38), we not distinguish these two upper bounds in this figure. It is observed that, the uplink throughput of $L = 3$ is slightly higher than that of $L = 2$ for the proposed GCICA-RA scheme. The reason is that the number of iterations of the SIC for $L = 2$ is larger than that for $L = 3$ on average, which results in the higher CSI estimation error [14] and further increase the equivalent noise introduced by the SIC algorithm. We also see that, the uplink throughput of the proposed GCICA-RA scheme is close to the upper bound, and significantly higher than those of baselines. With the increase of the number of active UEs, the gap between the uplink throughput of the proposed GCICA-RA scheme and those of baselines increases. This means that our proposed GCICA-RA is more suitable to crowded scenarios.

VI. CONCLUSION

An GCICA-RA grant-free scheme was proposed to support massive connectivity for M2M communications in massive MIMO systems. The GCICA-RA scheme allows each active UE to transmit their super pilots and modulated uplink messages to the BS. Based on the received pilot signal and modulated uplink message, the BS utilizes a proposed GCICA algorithm to estimate the CSI and decode the uplink message of each active UE jointly, and then employs the estimated CSIs to detect active UEs. Simulation results demonstrated that, our proposed GCICA-RA scheme achieves performance gain even in the very crowded scenarios.
