According to the topological band theory of a Hermitian system, the different electronic phases are classified in terms of topological invariants, wherein the transition between the two phases characterized by a different topological invariant is the primary signature of a topological phase transition. Recently, it has been argued that the delocalization-localization transition in a quasicrystal, described by the non-Hermitian $\mathcal{PT}$-symmetric extension of the Aubry-André-Harper (AAH) Hamiltonian can also be identified as a topological phase transition. Interestingly, the $\mathcal{PT}$-symmetry also breaks down at the same critical point. However, in this article, we have shown that the delocalization-localization transition and the $\mathcal{PT}$-symmetry breaking are not connected to a topological phase transition. To demonstrate this, we have studied the non-Hermitian $\mathcal{PT}$-symmetric AAH Hamiltonian in the presence of Rashba Spin-Orbit (RSO) coupling. We have obtained an analytical expression of the topological transition point and compared it with the numerically obtained critical points. We have found that, except in some special cases, the critical point and the topological transition point are not the same. In fact, the delocalization-localization transition takes place earlier than the topological transition whenever they do not coincide.

Introduction- The discovery of the connection between the electronic phases of a Hermitian system and the topology of its band structure has had far reaching consequences in a wide range of electronic phenomena, such as topological insulators [1–3], semimetals [4, 5] and superconductors [6]. In this approach, an electronic phase is characterized by a topological quantity which remains invariant under the continuous deformation of some control parameter in the Hamiltonian. A topological transition takes place whenever there is a change in the electronic phases, characterized by a different topologically invariant quantity, as the control parameter changes [7–10]. Naturally, the question arises regarding the existence of such topological transitions in a $\mathcal{PT}$-symmetric non-Hermitian system. In the last decade, several investigations on the topological phenomena in the non-Hermitian $\mathcal{PT}$-symmetric systems have been realized [11–14].

Recently, it has been pointed out that the delocalization-localization transition in a non-Hermitian $\mathcal{PT}$-symmetric extension of the Aubry-André-Harper (AAH) Hamiltonian can also be classified as a topological transition between the two topologically non-trivial phases characterized by a different topological invariant [15]. Moreover, the $\mathcal{PT}$-symmetry also breaks down at this critical point. Several instances of the topological transitions being accompanied with the localization-delocalization transition [16] and the existence of mobility edge [17] have been investigated for years. In a recent work [18], by introducing an additional non-hermiticity in the hopping parameters, it has been reported that the delocalization-localization is not necessarily in accordance with the topological phase transitions.

The objective of this Letter is to demonstrate that the localization-delocalization transition and the $\mathcal{PT}$-symmetry breaking are not related to a topological transition in the $\mathcal{PT}$-symmetric non-Hermitian quasicrystals which does not require any additional breaking of the hermiticity. To demonstrate this concretely, we have considered the non-Hermitian AAH Hamiltonian in the presence of the Rashba Spin-Orbit (RSO) coupling, conserving the $\mathcal{PT}$-symmetry of the system. As a first step, we obtain an analytical expression of the topological transition point. The critical point, which is also identical with the $\mathcal{PT}$-symmetry breaking point, is determined numerically. We have found that the critical point does not coincide with the analytically obtained topological transition point, except in some special cases.

Model- The Hamiltonian considered in this Letter originates from the model proposed by Longhi [15], comprising non-interacting electrons in an one-dimensional quasiperiodic lattice with a $\mathcal{PT}$ symmetric non-Hermiticity introduced in the cosine-modulated phase of the conventional AAH model [19, 20] and is given by,

$$H_A = -t \sum_{n=1,\sigma}^{L-1} (c_{n+1,\sigma}^\dagger c_{n,\sigma} + h.c) + \sum_{n=1,\sigma}^{L} V_n c_{n,\sigma}^\dagger c_{n\sigma}, \quad (1)$$

where t is the amplitude of hopping integral in the tight-binding Hamiltonian, and n is the lattice site index in the real space and L denotes the size of the lattice. $c_{n,\sigma}^\dagger$ and $c_{n,\sigma}$ represent the electronic creation and annihilation operators respectively at site n with spin state σ ($\sigma =\uparrow,\downarrow$). The non-Hermiticity is introduced in the form
FIG. 1. The variation of the critical value h_c with the strength of RSO coupling. The numerically calculated values of h_c have been shown by diamond shaped markers (in blue), and the analytical result of h_t from Eq. (23) has been represented by solid lines (in green). The results are for a lattice with 610 sites, and obeying the periodic boundary conditions. (a) and (b): Phase diagram of the critical points when one of the RSO hopping amplitude (α_y or α_z) is set to zero, while the other component varies with a non-zero amplitude. (d) and (e): Phase diagram of the critical points when α_y/t is set to 0.40 while the component α_z varies, and vice-versa. (c) and (f): Phase diagram of the critical points with t set to zero, and when α_y varies as a function of α_z and vice-versa.

of a complex phase in the on-site potential and is expressed as,

$$V_n = V\cos(2\pi\alpha n + \phi), \tag{2}$$

where $\phi = \theta + ih$. V is the amplitude of the modulation, and α is an irrational number from the Diophantine approximation ($\alpha = (\sqrt{5}+1)/2$). When $h = 0$, we get back the original Hermitian version of the AAH Hamiltonian. It is easy to see that H_A retains the $\mathcal{PT}$-symmetry after the introduction of this complex phase. In the presence of the RSO coupling, our Hamiltonian H consists of two parts, and is given by,

$$H = H_A + H_R, \tag{3}$$

where H_A is the non-Hermitian counterpart of the standard AAH Hamiltonian given by Eq. (1), and H_R includes the spin conserving hopping amplitude(α_y) and the spin-flip hopping amplitude(α_z) induced by RSO coupling and can be written as [21, 22],

$$H_R = -\alpha_z \sum_{n=1,\sigma,\sigma'}^{L-1} (c_{n+1,\sigma}^\dagger (i\sigma_y)_{\sigma,\sigma'} c_{n,\sigma'} + h.c.)$$
$$-\alpha_y \sum_{n=1,\sigma,\sigma'}^{L-1} (c_{n+1,\sigma}^\dagger (i\sigma_z)_{\sigma,\sigma'} c_{n,\sigma'} + h.c.). \tag{4}$$

To find the analytical expression of the topological transition point in the presence of RSO coupling, at first, we start with the eigenvalue equation $H\,|\Psi\rangle = E\,|\Psi\rangle$, where Ψ is a linear superposition of the spin states given by, $|\Psi\rangle = \sum_{n,\sigma} \psi_n^\sigma c_{n,\sigma}^\dagger |0\rangle$. Taking into account the two spin orientations, the set of coupled eigenvalue equations read as,

$$-t\left(\psi_{n+1}^\uparrow + \psi_{n-1}^\uparrow\right) + \alpha_y\left(e^{-i\pi/2}\psi_{n+1}^\uparrow + e^{i\pi/2}\psi_{n-1}^\uparrow\right)$$
$$+\alpha_z\left(\psi_{n+1}^\downarrow - \psi_{n-1}^\downarrow\right) + V\cos(2\pi\alpha n + \phi)\psi_n^\uparrow = E\psi_n^\uparrow, \tag{5}$$

$$-t\left(\psi_{n+1}^\downarrow + \psi_{n-1}^\downarrow\right) + \alpha_y\left(e^{-i\pi/2}\psi_{n+1}^\downarrow + e^{i\pi/2}\psi_{n-1}^\downarrow\right)$$
$$-\alpha_z\left(\psi_{n+1}^\uparrow - \psi_{n-1}^\uparrow\right) + V\cos(2\pi\alpha n + \phi)\psi_n^\downarrow = E\psi_n^\downarrow. \tag{6}$$

Multiplying i to Eq. (6) and adding it to Eq. (5), we obtain a single eigenvalue equation given by,

$$t'\left[e^{-i\eta}\tilde{\psi}_{n+1} + \tilde{\psi}_{n-1}e^{i\eta}\right] + V\cos(2\pi\alpha n + \phi)\tilde{\psi}_n = E\tilde{\psi}_n, \tag{7}$$

where $\tilde{\psi}_n = \psi_n^\uparrow + i\psi_n^\downarrow$, $t' = \sqrt{t^2 + (\alpha_y + \alpha_z)^2}$ and $\eta = \tan^{-1}\left[-(\alpha_y + \alpha_z)/t\right]$.
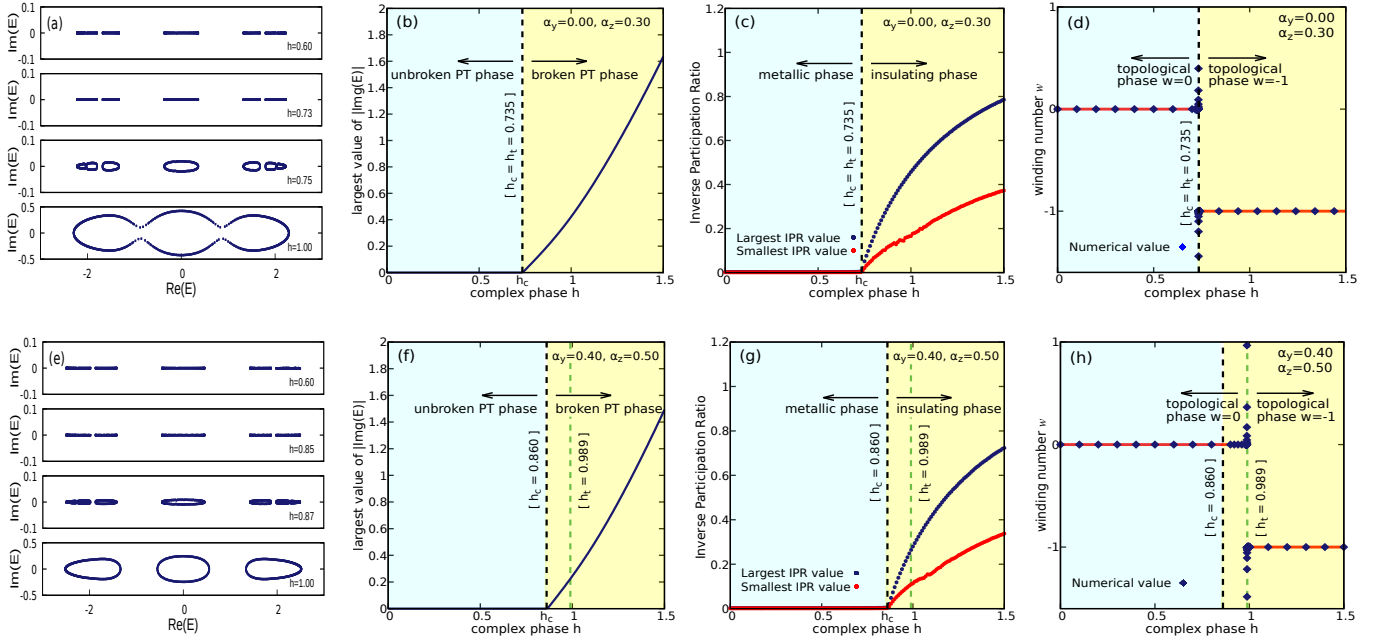

FIG. 2. Phase transition in non-Hermitian quasicrystals described by Eq. (10), where t has been set equal to V ($t=V=1$), and with $\theta = 0$. The upper panel is for the RSO coupling strength set at $\alpha_y = 0$ and $\alpha_z = 0.3$, while in the lower panel $\alpha_y = 0.4$ and $\alpha_z = 0.5$. (a) and (e): The energy spectrum spanned in the complex plane, with an increasing value of the control parameter h. (b) and (f): The nature of the largest value of $|Im(E)|$ *vs.* h across the PT symmetry breaking point. The horizontal black dotted line depicts the critical value h_c, whereas the green dotted line shows the transition point h_t determined analytically in Eq. (23). (c) and (g): Behavior of the largest(in blue) and smallest(in red) values of the Inverse Participation Ratio with an increasing value of h, before and after the metal-insulator transition. (d) and (h): The variation of numerically determined values of winding number $w(h)$ with h(in blue) and the analytical result from Eq. (25) shown as solid red line.

In the next step, we are going to show that the above eigenvalue equation is identical with the non-Hermitian $\mathcal{PT}$-symmetric AAH Hamiltonian expressed in Eq. (1). To do this, we obtain the eigenvalue equation in momentum space with the help of the Fourier transformation $\tilde{\psi}_n = \sum_k \tilde{\psi}_k e^{i(2\pi\alpha n)k}$ to get:

$$W_k\tilde{\psi}_k + \frac{V}{2}(e^{i\phi}\tilde{\psi}_{k+1} + \tilde{\psi}_{k-1}e^{-i\phi}) = E\tilde{\psi}_k, \quad (8)$$

where,

$$W_k = 2t'\cos(2\pi\alpha k - \eta), \quad (9)$$

and $\tilde{\psi}_k = \psi_k^\uparrow + i\psi_k^\downarrow$. In the final step, we apply an inverse Fourier transformation $\tilde{\psi}_k = \sum_n \tilde{\psi}_n e^{-i(2\pi\alpha k - \eta)n}$ on Eq. (8) to get:

$$t'\left[\tilde{\psi}_{n+1} + \tilde{\psi}_{n-1}\right] + V\cos(2\pi\alpha n + \phi)\tilde{\psi}_n = E\tilde{\psi}_n. \quad (10)$$

It is quite evident that the eigenvalue equation in Eq. (10) is identical with that of Eq. (1), with the rescaled hopping amplitude t' in lieu of the tight binding hopping amplitude t.

The common approach to identify the critical point in this type of quasicrystals is to find the Lyapunov exponent characterizing the inverse of the localization length [20, 23]. In Ref. [15] it has been established

that this approach is equally applicable for the original $\mathcal{PT}$-symmetric non-Hermitian AAH Hamiltonian without the RSO coupling. In this case, the Lyapunov exponent is given by $\gamma = \log(2t/V)$ and there is a phase transition from an extended/metallic ($V < 2t$) to a localized/insulating regime ($V > 2t$). Such a transition also coincides with the PT symmetry breaking point, at which the energy spectrum changes from real(and positive) to entirely complex [24, 25]. Since, in the presence of the RSO coupling, our Hamiltonian is equivalent to the original $\mathcal{PT}$-symmetric AAH Hamiltonian, it is anticipated that in the presence of the RSO coupling the $\mathcal{PT}$-symmetric non-Hermitian AAH Hamiltonian would undergo a similar delocalization-localization transition at $V = 2t'$. In this case, the Lyapunov exponent is given by, $\gamma = \log(2t'/V)$. However, we are going to show that this is *not true* in general. We have found that when either all the hopping amplitudes are non-zero or the tight-binding hopping amplitude is zero, the localization-delocalization transition and the $\mathcal{PT}$-symmetry breaking still coincide with each other, but takes place earlier than the anticipated value from the analysis of the Lyapunov exponent. Interestingly, however, we have found that the anticipated value of the transition point is associated with a topological transition. This *clearly* indicates that the delocalization-localization transition in the non-

Hermitian $\mathcal{PT}$-symmetric AAH Hamiltonian is not connected to a topological transition.

Behavior of the topological phases, symmetry breaking, metal-insulator transition and phase diagram in the presence of RSO- The method to classify the phases based on topology of the band structure is quite well established by now for the Hermitian systems [1, 10]. Recently, Gong *et al.* [26] have laid down a method for the topological classification of the electronic phases in non-Hermitian systems. Similar to the spirit for classifying phases in an Hermitian system, the above-mentioned method has been used in Ref. [15] to define a winding number, separating the two topological phases. Here, following the same approach laid down by Gong *et al.* [26] and Longhi [15], we assume the complex phase h as a control parameter of the Hamiltonian, where $H(\phi) = H(\theta, h)$ is given by,

$$
H = \begin{pmatrix}
V_1 & t' & 0 & 0 & 0 & ... & 0 & 0 & t' \\
t' & V_2 & t' & 0 & 0 & ... & 0 & 0 & 0 \\
0 & t' & V_3 & t' & 0 & ... & 0 & 0 & 0 \\
... & ... & ... & ... & ... & ... & ... & ... & ... \\
0 & 0 & 0 & 0 & 0 & ... & t' & V_{L-1} & t' \\
t' & 0 & 0 & 0 & 0 & ... & 0 & t' & V_L
\end{pmatrix} \quad (11)
$$

We begin with the definition of winding number $w(h)$ (for $h > 0$), given by,

$$
w(h) = \lim_{L\to\infty} \frac{1}{2\pi i f} \int_0^{2\pi} \partial_\theta \log\{\det[H(\theta/L, h) - E_b]\} d\theta
$$

$$
= \lim_{L\to\infty} \int_0^{2\pi} \frac{1}{2\pi i f}(\partial_\theta f) d\theta, \quad (12)
$$

where

$$
f(\theta, h) \equiv \log\{\det[H(\theta/L, h) - E_b]\}. \quad (13)
$$

In the above equation, E_b is a base energy, which lies inside the gaps of the energy spectrum of the Hermitian AAH Hamiltonian ($h = 0$). From the following discussion, it will be clear that the winding number is independent of the choice of E_b.

To calculate the winding number, however, it is convenient to use the momentum space form of $f(\theta, h) = \log\{\det[H_2 - E_b]\}$. Here, H_2 is connected to $H(\theta/L, h)$ through the similarity transformation $H = R^{-1} H_2 R$, where $R_{n,l} = (1/\sqrt{L}) \exp(2\pi i \alpha n l) \exp(-nh + in\theta/L)$. The transformed Hamiltonian H_2 is given by,

$$
H_2 = \begin{pmatrix}
W_1 & \frac{V}{2} & 0 & 0 & ... & 0 & 0 & \frac{V}{2} e^{hL} e^{-i\theta} \\
\frac{V}{2} & W_2 & \frac{V}{2} & 0 & ... & 0 & 0 & 0 \\
0 & \frac{V}{2} & W_3 & \frac{V}{2} & ... & 0 & 0 & 0 \\
... & ... & ... & ... & ... & ... & ... & ... \\
0 & 0 & 0 & 0 & ... & \frac{V}{2} & W_{L-1} & \frac{V}{2} \\
\frac{V}{2} e^{-hL} e^{i\theta} & 0 & 0 & 0 & ... & 0 & \frac{V}{2} & W_L
\end{pmatrix}
$$

where $W_k = 2t' \cos(2\pi\alpha k - \eta)$. It is easy to see that in the limit of large L ($L \to \infty$), $(H_2)_{L,1} \to 0$ and $f(\theta, h)$

can be written as,

$$
f(\theta, h) = \log\left\{(-1)^{L+1}\left(V/2\right)^L e^{hL} e^{-i\theta} + \det(\Theta - E_b)\right\}, \quad (14)
$$

where Θ is an Hermitian matrix given by,

$$
\Theta = \begin{pmatrix}
W_1 & \frac{V}{2} & 0 & 0 & 0 & ... & 0 & 0 & 0 \\
\frac{V}{2} & W_2 & \frac{V}{2} & 0 & 0 & ... & 0 & 0 & 0 \\
0 & \frac{V}{2} & W_3 & \frac{V}{2} & 0 & ... & 0 & 0 & 0 \\
... & ... & ... & ... & ... & ... & ... & ... & ... \\
0 & 0 & 0 & 0 & 0 & ... & \frac{V}{2} & W_{L-1} & \frac{V}{2} \\
0 & 0 & 0 & 0 & 0 & ... & 0 & \frac{V}{2} & W_L
\end{pmatrix} \quad (15)
$$

Since Eq. (15) is independent of θ, $f(\theta, h)$ can be written as,

$$
\frac{1}{2\pi i f}(\partial_\theta f) = \frac{1}{2\pi} \frac{(-1)^L \left(\frac{V}{2}\right)^L e^{hL} e^{-i\theta}}{(-1)^{L+1}\left(\frac{V}{2}\right)^L e^{hL} e^{-i\theta} + \det(\Theta - E_b)} \quad (16)
$$

The value of $\det(\Theta - E_b)$ can be estimated by identifying that

$$
\det(\Theta - E_b) = \exp(g), \quad (17)
$$

where

$$
g = \sum_L^{l=1} \log|\lambda_l - E_b|. \quad (18)
$$

Here, $\lambda_1, \lambda_2, \cdots, \lambda_L$ are the eigenvalues of the Hermitian matrix Θ for a one-dimensional lattice with L sites. As mentioned earlier, since the base energy is chosen inside the small gaps of the energy spectrum of Θ, the value of g never diverges. For a continuous energy spectrum, Eq. (18) can be expressed as,

$$
g = L \int d\epsilon \rho(\epsilon) \log|\epsilon - E_b|, \quad (19)
$$

where $\rho(\epsilon)$ is the density of states. It is now possible to estimate the Lyapunov exponent γ of an eigenstate of Θ around the neighbourhood of the base energy E_b, which is given by [27],

$$
\gamma = \int d\epsilon \rho(\epsilon) \log|\epsilon - E_b| - \log\left(\frac{V}{2}\right). \quad (20)
$$

Hence, $\det(\Theta - E_b)$ can be written as,

$$
\det(\Theta - E_B) = \left(\frac{V}{2}\right)^L \exp(\gamma L). \quad (21)
$$

It is well established that for the Hermitian AAH Hamiltonian without the RSO, γ is independent of the base energy and given by [20, 23],

$$
\gamma = \log\left(\frac{2t}{V}\right). \quad (22)
$$

This follows from the self-duality property of the Hermitian AAH Hamiltonian without the RSO interaction. Recently, we have shown that the Hermitian AAH Hamiltonian is self-dual in the presence of the RSO [28], which can also be deduced from Eq. (7). Hence, in the presence of the RSO coupling, the Lyapunov exponent γ is anticipated to be,

$$\gamma = \log\left(\frac{2t'}{V}\right) = \log\left(\frac{2t\sqrt{1+\left(\frac{\alpha_y+\alpha_z}{t}\right)^2}}{V}\right) \quad (23)$$

It is now straightforward to see from Eqs. (16) and (21) that,

$$\lim_{L\to\infty}\frac{1}{2\pi i f}(\partial_\theta f) = \begin{cases} 0 & \text{if } h < \gamma \\ -(1/2\pi) & \text{if } h > \gamma \end{cases} \quad (24)$$

From the definition of the winding number $w(h)$ in Eq. (12), we can expect a topological transition at a critical value of $h = h_t$,

$$w(h) = \begin{cases} 0 & \text{if } h < h_t \\ -1 & \text{if } h > h_t. \end{cases} \quad (25)$$

From the analytical result, it is evident that there exists a topological transition in quasicrystals described by the $\mathcal{PT}$-symmetric non-Hermitian AAH Hamiltonian with RSO coupling. We have also verified the topological transition point numerically, and found that indeed there is a topological transition at the crtical value given by h_t. However, we are going demonstrate that the critical point h_c, where the delocalization-localization transition takes place, does not coincide with the topological transition point in general, except in some special limiting cases. Moreover, $h_c < h_t$, whenever they do not coincide. We have also found that the $\mathcal{PT}$-symmetry always breaks down at h_c.

We now discuss our main results. Numerical methods to determine the critical point and the winding number have been discussed in the subsequent sections. The numerical results are for a lattice with L=610 sites, and obeying the periodic boundary conditions. In Fig. 1, we have presented the phase diagram in the space spanned by the parameters of the Hamiltonian in Eq. (3). In Figs. 2(a) and (b), we have presented the results of the numerically obtained critical points and compared it with the analytically obtained topological transition point for the two limiting cases: $\alpha_y = 0$ and $\alpha_z = 0$. From the analytical expression obtained in Eq. (23), it is obvious that in the presence of a single RSO coupling term, the critical value h_t can be expressed for the two different cases as, $h_t = \log(2\alpha_z/V)$, and $h_t = \log(2\alpha_y/V)$. The topological critical points h_t as a variation of α_z in the former, and with α_y in the latter is shown in Figs. 1(a) and (b), in which the analytical result matches exactly

with the critical points h_c computed numerically. However, when the contribution of both the spin-orbit coupling hopping amplitudes are non-zero, the topological critical point h_t and the delocalization-localization transition point h_c gets separated as can be seen from Figs. 1(d) and (e). Furthermore, it is also quite obvious that on interchanging the non-zero strengths of α_y and α_z, the existing conditions for the two types of transition remain unaffected. To understand the origin of this difference between h_c and h_t, we have shown the phase diagram in Figs. 1(c) and (f), when the tight binding hopping amplitude t is set to zero. It is clear that the critical points h_c follow exactly the same pattern as Figs. 1(a-b). However, the topological critical points are remarkably different, suggesting that the difference between h_c and h_t is due to the combined effect of the two hopping processes of the RSO Hamiltonian.

To identify the localization of the eigenstates, we use the familiar approach of the Inverse Particpation Ratio(IPR) [29, 30] given by,

$$IPR = \frac{\sum_n |\psi_n|^4}{(\sum_n |\psi_n|^2)^2} \quad (26)$$

It is well established that for extended states, the IPR varies with the system size as $N^{-1} \simeq 0$ (in the thermodynamic limit), whereas for localized states, the IPR is system size independent and approaches 1 when they are completely localized. For RSO, where the size of the Hamiltonian matrix $N = 2L$, these characteristics remain unaffected, with an enhancement in the delocalized regime upto the critical point h_c. Additionally, in the $\mathcal{PT}$-symmetric non-Hermitian quasicrystals, we expect the $\mathcal{PT}$-symmetry to be broken at some critical value of h, when the energy spectrum becomes complex. In Fig. 2(a), the energy spectrum in the complex plane, when a single RSO hopping amplitude (α_z) is non-zero, has been shown. It is clear that as h crosses beyond the value 0.73 ± 0.01, the entire energy spectrum becomes complex. For $\alpha_y = 0, \alpha_z = 0.3$ we estimate this transition point to be $h_t = 0.73 \pm 0.01$. We have further corroborated our observation by plotting the the largest value of $|\text{Im}(E)|$ vs. the complex phase h, as shown in in Fig. 2(b). The rapid increase in its value from zero suggests the transition from the unbroken PT symmetry regime to the broken PT symmetry regime at $h_c = 0.73 \pm 0.01$.

To detect the delocalization-localization transition point, the largest and the smallest values of the IPR have been plotted with h in Fig. 2(c). These results clearly indicate the existence of the localization transition exactly at the same critical point $h_c \simeq 0.74$ where the $\mathcal{PT}$-symmetry breaks down. On substituting $\alpha_y = 0$ and $\alpha_z = 0.3$ in the analytical expression of the topological critical point (Eq. 23), we obtain $h_t = 0.736$ (evaluated upto the third decimal place).Interchanging the values of α_y and α_z does not alter the critical point and the topo-

logical transition point, which are identical. Hence, in this case the critical point, the $\mathcal{PT}$-symmetry breaking point and the topological transition point are identical. However, this behaviour changes dramatically when both the hopping amplitudes of the RSO Hamiltonian are non-zero.

In the lower panel of Fig.(2), we have presented the results when both the RSO coupling strengths are considered to be non-zero. Figs. 2(e-g) show the same result corresponding to the Figs. 2(a-c), except that the localization transition point shifts, outstretching the metallic and PT-symmetry unbroken regimes to a higher value of h_c. In Fig. 2(f) and (g), we have also indicated the topological transition point h_t anticipated from our analytical result. It is evident that $h_c < h_t$ when both the RSO coupling have non-zero amplitudes. In Figs. 2(d) and (h), we have presented the results of the winding number that have been computed numerically. The evidence of the topological transition at the anticipated value of h from our analytical result obtained in Eq. (23) is obvious.

Conclusions- In summary, we have demonstrated that the delocalization-localization and the PT symmetric breaking transitions are not connected to a topological transition in the $\mathcal{PT}$-symmetric non-Hermitian quasicrystals. The topological transition point h_t has been obtained analytically by mapping the Hamiltonian in the presence of RSO to the original $\mathcal{PT}$-symmetric non-Hermitian AAH Hamilton and have been verified numerically. The critical point h_c has been determined numerically, and we have found that in general the delocalization-localization transition and the PT symmetric breaking takes place earlier than the topological phase transition, except in some special cases, although the delocalization-localization transition and the PT symmetric breaks simultaneously. *Acknowledgement*-
