Abstract

In a graph $G = (V, E)$ with no isolated vertex, a dominating set $D \subseteq V$, is called a *semitotal dominating set* if for every vertex $u \in D$ there is another vertex $v \in D$, such that distance between u and v is at most two in G . Given a graph $G = (V, E)$ without isolated vertices, the MINIMUM SEMITOTAL DOMINATION problem is to find a minimum cardinality semitotal dominating set of G . The *semitotal domination number*, denoted by $\gamma_{t2}(G)$, is the minimum cardinality of a semitotal dominating set of G . The decision version of the problem remains NP-complete even when restricted to chordal graphs, chordal bipartite graphs, and planar graphs. Galby et al. in [6] proved that the problem can be solved in polynomial time for bounded MIM-width graphs which includes many well known graph classes, but left the complexity of the problem in strongly chordal graphs unresolved. Henning and Pandey in [20] also asked to resolve the complexity status of the problem in strongly chordal graphs. In this paper, we resolve the complexity of the problem in strongly chordal graphs by designing a linear-time algorithm for the problem.

1 Introduction

A *dominating set* in a graph $G = (V, E)$, is a set $D \subseteq V$, such that any vertex not in D is adjacent to a vertex in D . The minimum size of a dominating set is called *domination number*, denoted by $\gamma(G)$. The MINIMUM DOMINATION problem involves computing a minimum cardinality dominating set of a graph G . The domination number is one of the most studied parameter in the graph theory. A thorough treatment and detailed study on domination can be found in the books [8, 9, 10, 11]. Due to numerous applications in the real world problems, many researchers introduced several variations of domination by imposing one or more additional conditions on dominating set. One of the most important variation of domination is total domination.

In a graph $G = (V, E)$, without isolated vertices, a dominating set $D \subseteq V$ is called a *total dominating set* (TD-set in short), if $G[D]$, the graph induced by D in G has no isolated vertex. The *total domination number*, denoted by $\gamma_t(G)$, is the cardinality of a minimum total dominating set of G . The MINIMUM TOTAL DOMINATION problem requires to compute a total dominating set of a graph G with no isolated vertex, of size $\gamma_t(G)$. See [13, 21] for the detailed results on total domination.

Goddard, Henning, and McPillan, introduced a relaxed notion of total domination, called *semitotal domination* in [7] and further studied in [6, 12, 14, 15, 16, 17, 18, 19, 20, 23, 28, 29, 32], from both algorithmic and combinatorial point of view. In a graph G with no isolated vertices, a *semitotal dominating set* (in short, semi-TD-set) is a dominating set $D \subseteq V$ such that for every vertex $u \in D$, there is another vertex $v \in D$, such that the distance between u and v is at most two in G . The *semitotal domination number*, denoted by $\gamma_{t2}(G)$, is the cardinality of a minimum semi-TD-set of G . It follows directly from definitions that every total dominating set is a semitotal dominating set. Hence, for a graph G with no isolated vertices, we have the following relation between the three parameters:

$$\gamma(G) \leq \gamma_{t2}(G) \leq \gamma_t(G).$$

Therefore, the semitotal domination number is squeezed between two important parameters, domination number and total domination number. The minimum semitotal domination problem and its decision version are defined as follows:

MINIMUM SEMITOTAL DOMINATION problem

Instance: A graph $G = (V, E)$ with no isolated vertices.

Solution: A Semi-TD-set D of G .

Measure: Cardinality of the set D .

SEMITOTAL DOMINATION DECISION problem

Instance: A graph $G = (V, E)$ and a positive integer $k \leq |V|$.

Question: Does there exist a Semi-TD-set D in G such that $|D| \leq k$?

The SEMITOTAL DOMINATION DECISION problem is NP-complete [7] for general graphs. The problem remains NP-complete, even when restricted to chordal graphs, chordal bipartite graphs, and planar graphs [20]. On positive side, we have polynomial-time algorithms to compute a minimum cardinality semi-TD-set in trees [7], interval graphs [20, 28] and block graphs [19]. Galby et al. [6] proved that, a minimum semi-TD-set can be computed in polynomial-time in bounded MIM-width graphs, which includes many important graph classes. The complexity status of the problem in some well known graph classes is shown in Fig. 1. In the figure, P stands for polynomial-time and NPC stands for NP-complete. The complexity status of the problem in graph classes with question mark is still unknown.

Henning and Pandey studied the approximation hardness of MINIMUM SEMITOTAL DOMINATION problem [20]. They proved that the problem can not be approximated within $(1 - \epsilon)\ln(|V|)$ for any $\epsilon > 0$, unless $\text{NP} \subseteq \text{DTIME}(|V|^{O(\log \log(|V|))})$. On other side, they proved that the MINIMUM SEMITOTAL DOMINATION problem is in the class log-APX. They also proved that the problem is APX-complete for the bipartite graphs with maximum degree 4.

Although, we have noticed that the semitotal domination number is squeezed between domination number and total domination number. But, MINIMUM SEMITOTAL DOMINATION problem and MINIMUM TOTAL DOMINATION problem differs in complexity, see [20]. Indeed, the MINIMUM TOTAL DOMINATION problem is polynomial-time solvable in chordal bipartite graphs but decision version of MINIMUM SEMITOTAL DOMINATION is NP-complete for chordal bipartite graphs. Further, Galby et al. proved that it is NP-hard to decide $\gamma_{t2}(2) = \gamma_t(G)$, even when G is a planar graph with degree at most 4, see [6].

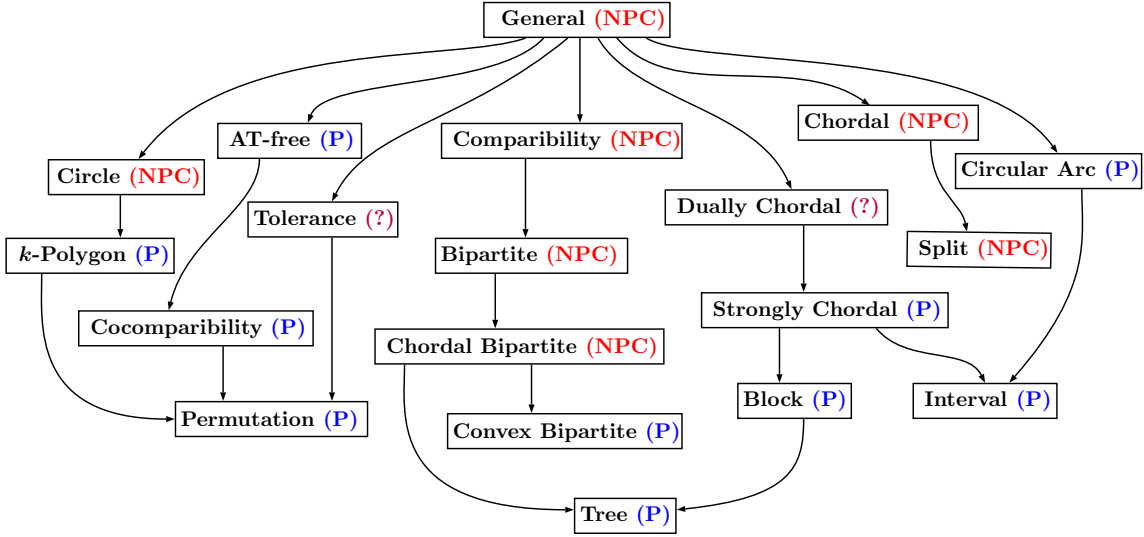

Figure 1: Complexity status of MINIMUM SEMITOTAL DOMINATION problem in some well known graph classes.

As the MIM-width of strongly chordal graphs is unbounded, the complexity of the problem was left open in strongly chordal graphs by Galby et al. [6]. Henning and Pandey in [20], also asked to find the complexity status of the problem in strongly chordal graphs. In this paper, we prove that the MINIMUM SEMITOTAL DOMINATION problem can be solved in linear-time in strongly chordal graphs.

The further structure of the paper is as follows. In Section 2, we discuss some notations and definitions. In Section 3, we discuss strongly chordal graphs and their properties. In Section 4, we design a linear-time algorithm to compute a semi-TD-set in strongly chordal graphs. Finally, Section 5, concludes the paper.

2 Preliminaries

Let $G = (V, E)$ be a simple graph, where $V = V(G)$ and $E = E(G)$. Two distinct vertices $u, v \in E(G)$, said to be *adjacent* if $uv \in E(G)$. For a vertex $v \in V$, the set $N_G(v) = \{u \in V \mid uv \in E(G)\}$ denotes the *open neighbourhood* of v in G and the set $N_G[v] = N_G(v) \cup \{v\}$ denotes the *closed neighbourhood* of v in G . A *path* $P = v_0v_1 \dots v_k$, is a sequence of distinct vertices, such that $v_{i-1}v_i \in E(G)$, where $1 \leq i \leq k$ and $k \geq 2$. Such a path, is called, a path between v_0 and v_k . We denote $V(P) = \{v_0, v_1, \dots, v_k\}$. The length of the path P is $|V(P)| - 1$. The distance between two distinct vertices $u, v \in V(G)$, denoted by $d_G(u, v)$, is the length of the shortest path between u and v in G . Further, we call u , a *distance two neighbour* of v , if $d_G(u, v) \leq 2$.

A path $P = v_0v_1 \dots v_k$ with an additional condition that, $v_0v_k \in E(G)$ is known as a *cycle* on k -vertices, denoted by C_k . In a cycle C_k , where $k \geq 4$, a *chord* is an edge joining two non-consecutive vertices of C_k . A graph G is called *chordal*, if any cycle of length at least 4 in G , has a chord.

Let $|V(G)| = n$, and $\beta = (v_1, v_2, \dots, v_n)$ be any ordering of the vertex set $V(G)$. For a vertex v_i in the ordering β , we define the sets $N_i(v_i) = \{v_j \mid j > i \text{ and } v_iv_j \in E(G)\}$ and $N_i[v_i] = N_i(v_i) \cup \{v_i\}$. Further, we define, $N_i^2(v_i) = \{v_j \mid j > i \text{ and } d_G(v_i, v_j) \leq 2\}$ and $N_i^2[v_i] = N_i^2(v_i) \cup \{v_i\}$.

For other notations and graph theoretic terminology, we refer [21]. In this paper, we consider only simple and connected graphs with at least 3 vertices. Also, for a positive integer n , we use the standard notation, $[n] = \{1, 2, \dots, n\}$.

3 Strongly Chordal Graphs

Strongly chordal graphs is an important subclass of chordal graphs introduced by several researchers in the literature [3, 5, 22]. Strongly chordal graphs includes interval graphs, block graphs, directed path graphs, and trees as subclass. Many variations of domination are polynomial-time solvable on strongly chordal graphs, see [2, 3, 4, 24, 25, 31]. There are many equivalent definitions of strongly chordal graphs. We follow, the definition given in [5].

Let $G = (V, E)$ be a graph. A vertex $v \in V$ is called *simple* if the vertices in the closed neighbourhood of v can be ordered, $N_G[v] = \{v_1, v_2, \dots, v_r\}$ where $v_1 = v$, such that $N_G[v_i] \subseteq N_G[v_j]$ for $1 \leq i \leq j \leq r$. A graph G is *strongly chordal* if every induced subgraph of G has a simple vertex. An ordering $\alpha = (v_1, v_2, \dots, v_n)$ of vertices of V is called *strong elimination ordering*(SEO) if $v_j, v_k \in N_i[v_i]$ implies $N_i[v_j] \subseteq N_i[v_k]$ for $1 \leq i \leq j \leq k \leq n$.

Many algorithms are studied to recognise a strongly chordal graph, $G = (V, E)$. In [1, 22], the authors designed an $O(|V|^3)$ -time algorithm to recognise a strongly chordal graph. In [26], a $O(|E|(\log|E|)^2)$ -time algorithm is given which later, improved to $O(|E|\log|E|)$ -time algorithm in [27]. Spinrad in [30], gave an $O(n^2)$ -time algorithm to recognise a strongly chordal graph. The same algorithm also computes, a strong elimination ordering, if the graph is strongly chordal. The graph in Fig. 2, is a strongly chordal graph with strong elimination ordering $\alpha = (v_1, v_2, v_3, v_4, v_5, v_6, v_7, v_8)$.

Figure 2: An example of a strongly chordal graph.

Given a strongly chordal graph $G = (V, E)$ and a strong elimination ordering $\alpha = (v_1, v_2, \dots, v_n)$ of the vertex set V , we have the following observation.

Observation 3.1. *If $v_i v_j \in E(G)$ such that $i < j$, then $N_i[v_i] \subseteq N_i[v_j]$. Further, if $F(v_i) = v_k$ then $N_i[v_j] \subseteq N_i[v_k]$.*

Let $G = (V, E)$ be a strongly chordal graph and $\alpha = (v_1, v_2, \dots, v_n)$ be its SEO. For a vertex $v_i \in V$, $F(v_i)$ denotes the highest index neighbour of v_i according to SEO, where $i < n$. In particular $F(v_n) = v_n$. Our algorithm is an iterative algorithm which process the vertices as they appear in SEO. We use the following labels on the vertices during the execution of the algorithm to construct a minimum semi-TD-set of G .

$$D(v_i) = \begin{cases} 0 & \text{if } v_i \text{ is not dominated,} \\ 1 & \text{if } v_i \text{ is dominated.} \end{cases}$$

$$L(v_i) = \begin{cases} 0 & \text{if } v_i \text{ is not selected,} \\ 1 & \text{if } v_i \text{ is selected but no vertex } u \text{ is selected such that } d_G(u, v_i) \leq 2, \\ 2 & \text{if } v_i \text{ is selected and a vertex } u \text{ is also selected such that } d_G(u, v_i) \leq 2. \end{cases}$$

$$m(v_i) = \begin{cases} k & \text{if vertex } v_k \in N_G[v_i] \text{ is selected but a vertex } u \text{ need to be selected such that } d_G(u, v_k) \leq 2, \\ 0 & \text{otherwise.} \end{cases}$$

Further, $B_i[v_i]$ represents the set of neighbours v_k of v_i such that $N_i[F(v_i)] \subseteq N_i[v_k]$ and one of the neighbour of v_k is already dominated. Formally, $B_i[v_i] = \{v_k \in N_i[v_i] \mid N_i[F(v_i)] \subseteq N_i[v_k] \text{ and there is a vertex } w \in N_G[v_k] \text{ such that } D(w) = 1\}$. We note that, if $v_k \in B_i[v_i]$ then $N_i[F(v_i)] \subseteq N_i[v_k]$. Also by Observation 3.1, $N_i[v_k] \subseteq N_i[F(v_i)]$. Hence, for a vertex $v_k \in B_i[v_i]$, we have $N_i[v_k] = N_i[F(v_i)]$. In our algorithm, we also use two special types of operation on a particular vertex v_i , MARK(v_j) and UNMARK(v_j) which are defined as follows: if $F(v_i) = v_j$ then the operation MARK(v_j) updates $m(v_k) = i$ for all $v_k \in N_G[v_j]$ such that $k > i$. While in operation UNMARK(v_j) we update $m(v_k) = 0$ for all $v_k \in N_G[v_j]$. Before designing the algorithm, we first prove the following results.

Lemma 3.1. *For a vertex v_i , let $F(v_i) = v_j$ such that $i < j$ then $N_i^2[v_i] \subseteq N_i[v_j]$.*

Proof : Since $v_i v_j \in E(G)$, $N_i[v_i] \subseteq N_i[v_j]$ using the property of SEO. Now, consider a vertex $v_t \in V(G)$ such that $d_G(v_i, v_t) = 2$ and $t > i$. Let $P = v_i v_s v_t$ be a shortest path between v_i and v_t . An illustration of possible positions of v_t is given in Fig. 3. As v_j is the highest index neighbour of v_i , we have $s \leq j$. Indeed, $s > i$, as if $s < i$ then using property of SEO we have $v_i v_t \in E(G)$, a contradiction. Hence, we have $i < s < j$, implying that $N_i[v_s] \subseteq N_i[v_j]$. Consequently, we have $v_i v_j \in E(G)$. Hence, the result follows. \square

Figure 3: Positions of v_t , when $d_G(v_i, v_t) = 2$ in Lemma 3.1

Lemma 3.2. *If $v_i v_j \in E(G)$ such that $i < j$ then $N_i^2[v_i] \subseteq N_i^2[v_j]$.*

Proof : Let $F(v_i) = v_k$ in the SEO. Clearly, $j \leq k$ and using property of SEO, $N_i[v_i] \subseteq N_i[v_j] \subseteq N_i[v_k]$. Let $v_t \in N_i^2[v_i]$ be an arbitrary vertex. If $v_i v_t \in E(G)$, then $v_j v_t \in E(G)$ as $N_i[v_i] \subseteq N_i[v_j]$. Now suppose, $d_G(v_i, v_t) = 2$ and $P = v_i v_s v_t$ be a shortest path between v_i and v_t . Clearly $s > i$. Since $N_i[v_i] \subseteq N_i[v_j]$, we have $v_s v_j \in E(G)$. Hence, $d_G(v_t, v_j) \leq 2$. Therefore, the lemma follows. \square

Lemma 3.3. *If $v_i v_j \in E(G)$ such that $i < j$ and $F(v_j) = v_k$ then $N_i^2[v_i] \subseteq N_i^2[v_k]$.*

Proof : Using property of SEO, we note that $N_i[v_i] \subseteq N_i[v_j]$. Therefore, for any vertex $v_r \in N_i[v_i]$, we have $d_G(v_k, v_r) \leq 2$. Now consider a vertex v_t such that $d_G(v_i, v_t) = 2$ and $t > i$. Let $P = v_i v_s v_t$ be a shortest path between v_i and v_t . If $s < i$, then using the property of SEO, we have $v_i v_t \in E(G)$, a contradiction. Hence, $s > i$. Now, if $s \leq j$ then using property of SEO, $N_i[v_s] \subseteq N_i[v_j]$, implying that $d_G(v_k, v_t) \leq 2$. Further, if $s > j$ then $N_i[v_j] \subseteq N_i[v_s]$. This implies that $v_j v_s \in E(G)$ and hence, $v_s v_k \in E(G)$. Consequently, we have $d_G(v_k, v_t) \leq 2$. Therefore the lemma follows. \square

Lemma 3.4. *If for a vertex v_i , $F(v_i) = v_j \neq v_i$ and $v_k \in N_i[v_i]$ then $N_i^2[v_k] \subseteq N_i^2[v_j]$.*

Proof : The proof directly follows from the property of strong elimination ordering. For completeness, suppose $v_r \in N_i^2[v_k]$. We note that $N_i[v_k] \subseteq N_i[v_j]$. Hence, if $v_k v_r \in E(G)$, Lemma follows. Now, assume that $d_G(v_k, v_r) = 2$ where $r \geq i$. Let $P = v_r v_a v_k$ be a shortest path of length two in G . As $k, r \geq i$, if $a < i$ then using property of SEO, we have $v_r v_k \in E(G)$, a contradiction. Hence, $a \geq i$. Further, using fact that, $N_i[v_k] \subseteq N_i[v_j]$, we have $v_a v_j \in E(G)$. Consequently, we have $d_G(v_r, v_j) \leq 2$. \square

Lemma 3.5. *If for a vertex v_i , we have $F(v_i) = v_i$ then $i = n$.*

Proof : On contrary, suppose $F(v_i) = v_i$ but $i \neq n$. Now since the graph is connected there exists a path joining the vertices v_i and v_{i+1} . Suppose, P is a shortest such path. Note that the path must contain a vertex v_j such that $j < i$ and a vertex v_k such that $k > i$. Let v_j be the highest index vertex and v_k be the least index in the path such that $v_j v_k \in E(G)$. Since, P is a shortest path, we have $P = v_i v_{i_1} v_{i_2} \dots v_{i_r} v_j v_k v_{k_1} v_{k_2} \dots v_{k_{r'}} v_{i+1}$ where $j < i_r < i_{r-1} < \dots < i_1 < i < i+1 < k_{r'} < \dots < v_{k_1} < v_k$. An illustration is given in Fig. 4. As $v_j v_k \in E(G)$, therefore, using the property of SEO, we have $v_{i_r} v_k \in E(G)$, a contradiction on choice of P . Hence, the result follows. \square

Figure 4: An illustration of path in Lemma 3.5

Lemma 3.6. *Let $G = (V, E)$ be a connected strongly chordal graph and $\alpha = (v_1, v_2, \dots, v_n)$ be an SEO of G . For a vertex v_i , let $F(v_i) = v_j$. Suppose there is a path $P = v_i v_{i_1} v_{i_2} \dots v_{i_j} v_k$ from v_i to a vertex v_k such that $k < i_1 < i_2 < \dots < i_j < i$. If v_k has a neighbour v_s such that $s \geq i$ then $d_G(v_k, v_j) \leq 2$. Specifically, $v_i v_s, v_j v_s \in E(G)$.*

Proof : The proof directly follows using property of strong elimination ordering. Hence, omitted. \square

4 Algorithm for Semitotal Domination in Strongly Chordal Graphs

In this section, we propose, a linear-time algorithm to compute a minimum semi-TD-set in strongly chordal graphs. But, before designing the algorithm first, we discuss the idea of the algorithm.

Outline of the Algorithm

Let $G = (V, E)$ be a strongly chordal graph and $\alpha = (v_1, v_2, \dots, v_n)$ be a strong elimination ordering of the vertex set of G . In our algorithm, we process the vertices iteratively as they appear in α

and in each iteration we maintain a set D_{st} containing the selected vertices. In the i^{th} -iteration we will process the vertex v_i . We ensure that the vertices having index at most $i - 1$ are dominated by at least one vertex of D_{st} . Now in i^{th} -iteration, we update the set D_{st} in the following way:

1. If the vertex v_i is not dominated, and v_i is not the last vertex, then we look for a vertex such that, $N_i[v_k] \subseteq N_i[F(v_j)]$ and there exists a vertex in D_{st} which is at distance at most two from v_k .
 - If such a vertex v_k exists, we include it in D_{st} . We maintain the information that all the neighbours of v_k are dominated now. Also, as there is already a vertex in D_{st} which is at distance at most 2 from v_k , we maintain the information that a distance two neighbour of v_k is already selected. In the same iteration, we also check if there is a vertex $u \in D_{st}$, such that distance two neighbour of u is not selected till $(i - 1)^{th}$ -iteration. If such a vertex exists, and $d_G(u, v_k) \leq 2$, then for all such vertices u , we update the information that a distance two neighbour of u is selected, by updating $L(u) = 2$ and UNMARK(u)-operation.
 - Otherwise, we include $F(v_i)$ in D_{st} to dominate v_i and updated the information that all the neighbours of $F(v_i)$ are dominated now. Further, using MARK($F(v_i)$) operation, we also maintain the information that we need to select a distance two neighbour of $F(v_i)$, in one of the further iterations.
2. If the vertex v_i is not dominated, and v_i is the last vertex, that is, $v_i = v_n$, then we include v_n in the D_{st} . We update the status of v_n as dominated. Also, we may note that, all neighbours of v_n are already dominated. Hence, there is a vertex in D_{st} which is at distance at most 2 from v_n . Therefore, we updated $L(v_n) = 2$.
3. If v_i is already dominated and $m(v_i) = 0$, then we do not need to update D_{st} .
4. If v_i is already dominated and $m(v_i) = k \neq 0$, that is, v_k is selected in D_{st} and a distance two neighbour of v_k is still need to be selected then we updated D_{st} as follows:
 - If i is less than the index of $F(v_k)$, we simply update $m(v_k) = 0$.
 - If $v_i = F(v_k)$ and $F(v_i) = v_i$ then as v_i is the last vertex, we include any neighbour of v_i in D_{st} and update $m(v_i) = 0$.
 - If $v_i = F(v_k)$ and $F(v_i) \neq v_i$ then we include the highest index neighbour, $F(v_i)$ of v_i in D_{st} . We update the information that all the neighbour of $F(v_i)$ are dominated now. We also update the information that a distance two neighbour of v_k is selected by updating $L(v_k) = L(F(v_i)) = 2$ and UNMARK(v_k) operation. For all vertices, $u \in D_{st}$, such that distance two neighbour of u is not selected till $(i - 1)^{th}$ -iteration and $d_G(u, v_k) \leq 2$, we update that a distance two neighbour of u is selected, by updating $L(u) = 2$ and UNMARK(u)-operation.

Algorithm

Now, we design a linear-time algorithm, Algorithm 1, to compute a minimum semi-TD-set in a strongly chordal graph, given its strong elimination ordering.

Algorithm 1 Minimum Semitotal Domination in Strongly Chordal Graphs

Input: A Strongly Chordal graph $G = (V, E)$ and a SEO $\alpha = (v_1, v_2, \dots, v_n)$ of G

Output: A minimum cardinality semi-TD-set D_{st} of G .

for $i = 1$ **to** n **do**

if $(D(v_i) = 0$ **and** $F(v_i) \neq v_i)$ **then**

 Compute $B_i[v_i]$;

if $(B_i[v_i] = \emptyset)$ **then**

$L(F(v_i)) = 1$; // Let $F(v_i) = v_j$

 MARK(v_j);

$D(u) = 1 \forall u \in N_G[v_j]$;

else

 Let $k = \max\{k' \mid v_{k'} \in B_i[v_i]\}$;

$L(v_k) = 2$;

$D(u) = 1 \forall u \in N[v_k]$;

 Let $C = \{v_r \mid v_r \in N[v_k] \text{ and } m(v_r) \neq 0\}$;

while $(C \neq \emptyset)$ **do**

 Let $v_r \in C$ such that $m(v_r) = s$;

$L(v_s) = 2$;

 UNMARK(v_s);

$C = C \setminus \{v_r\}$;

else if $(D(v_i) = 0$ **and** $F(v_i) = v_i)$ **then**

$L(v_i) = 2$;

$D(v_i) = 1$;

else if $(D(v_i) = 1$ **and** $m(v_i) \neq 0)$ **then**

 Let $m(v_i) = s \neq 0$ **and** $F(v_s) = v_t$ where $t \geq s$;

if $(i < t)$ **then**

$m(v_i) = 0$;

else if $(i = t$ **and** $F(v_i) = v_i)$ **then**

$L(u) = 2$ for some $u \in N[v_i]$;

$L(v_s) = 2$ **and** $m(v_i) = 0$;

else

$L(F(v_i)) = 2$;

$L(v_s) = 2$;

$D(u) = 1$ for all $u \in N[F(v_i)]$;

 Let $C = \{v_r \mid v_r \in N[F(v_i)] \text{ and } m(v_r) \neq 0\}$;

while $(C \neq \emptyset)$ **do**

 Let $v_r \in C$ such that $m(v_r) = s'$;

$L(v'_s) = 2$;

 UNMARK(v'_s);

$C = C \setminus \{v_r\}$;

Let $D_{st} = \{v_i \in V \mid L(v_i) = 2\}$;

return D_{st} ;

Now to show the correctness of Algorithm 1 and to prove that given a strongly chordal graph G and its strong elimination ordering α , it computes a minimum semi-TD-set of G , we prove the following lemmas (Lemma 4.1 to Lemma 4.6).

Lemma 4.1. *At the beginning of the i^{th} -iteration, the following statements are true:*

1. $D(v_j) = 1$ for all $j \in [i - 1]$.
2. $m(v_j) = 0$ for all $j \in [i - 1]$.
3. If $L(v_k) = 1$ for $k < i$, then there exists a neighbour $v_{k'}$ of v_k such that $m(v_{k'}) = k$ and $k' \geq i$.

Proof : The proof directly follows from Algorithm 1. □

For each $i \in [n]$, let $D_i = \{v_j \in V(G) \mid L(v_j) > 0\}$ be the set of selected vertices after the i^{th} -iteration of the algorithm. Indeed, $D_n = \{v_j \in V(G) \mid L(v_j) > 0\}$ is the set of vertices selected by the algorithm after all the vertices are processed. In particular, suppose $D_0 = \emptyset$. In order to prove the correctness of the algorithm first we will show that D_n is a semi-TD-set of G and then we will show that D_i is contained in a minimum semi-TD-set of G for each $i \in ([n] \cup \{0\})$.

Lemma 4.2. D_n is a semi-TD-set of strongly chordal graph G .

Proof : In the i^{th} -iteration of the algorithm, we process the vertex v_i . First we check whether the vertex v_i is dominated or not using the vertices selected till $(i - 1)^{\text{th}}$ -iteration. Indeed, in the i^{th} -iteration, $D(v_i) = 0$ represents that the vertex v_i is not dominated by the current set D_{i-1} and hence, we pick a neighbour of v_i to dominate v_i . As we visit every vertex in some iteration, after the n^{th} -iteration, all vertices will be dominated by set D_n . Further in any iteration, if we pick any vertex v_s such that no vertex v_r is already selected such as $d_G(v_r, v_s) \leq 2$ then we perform MARK(v_s) operation. Let $F(v_s) = v_t$. According to the algorithm, we select a vertex u such $d_G(v_s, u) \leq 2$ in some j^{th} -iteration where $j \leq t \leq n$ and update $L(v_s) = 2$. Hence, after the n^{th} -iteration we note that $L(v_i) = 0$ or 2 for all $i \in [n]$. Hence D_n is a semi-TD-set of G . □

Using Lemma 4.2, we note that the set D_n is a semi-TD-set of the strongly chordal graph G . Now we claim that for each $i \in ([n] \cup \{0\})$, there is a minimum semi-TD-set D' of G containing D_i . We will prove this using induction on i . If $i = 0$, $D_0 = \emptyset$ is contained in any minimum semi-TD-set of G . Now we assume that there is minimum semi-TD-set D of G containing D_{i-1} . In the i^{th} iteration, depending upon the several cases of the algorithm we prove the following lemmas to show that there is a minimum semi-TD-set D' of G containing D_i .

Lemma 4.3. *If $D(v_i) = 0$, $F(v_i) \neq v_i$, and $B_i[v_i] = \emptyset$ then there exists a minimum semi-TD-set D' of G such that $(D_{i-1} \cup \{F(v_i)\}) \subseteq D'$.*

Proof : Using induction hypothesis, we have a minimum semi-TD-set D of G containing D_{i-1} . Clearly, if $F(v_i) \in D$ then $D' = D$ is the required minimum semi-TD-set. Hence, we assume that $F(v_i) \notin D$. Let $F(v_i) = v_j$. Since $F(v_i) \neq v_i$, $j > i$. Let v_k and v_l be the minimum index vertices in D dominating v_i and v_j respectively. We note that $l, k \neq j$. Now we prove the result by considering the following two cases:

Case 1: If $v_k = v_l$

In this case v_k is the least index vertex in D dominating both v_i and v_j . As $v_j = F(v_i)$ and $k \neq j$, therefore $k < j$. Indeed $v_k \notin D_{i-1}$ as if $v_k \in D_{i-1}$ then $D(v_i) = 1$, a contradiction. Further, if $k < i$ then using Lemma 4.1, we have $D(v_k) = 1$. Since $N_i[v_j] \subseteq N_i[v_k]$ and $v_k v_j \in E(G)$ with $D(v_k) = 1$ hence, $v_j \in B_i[v_i]$, a contradiction as $B_i[v_i] = \emptyset$. Therefore $k \geq i$. As $v_k, v_j \in N_i[v_i]$ and $i \leq k < j$, using the property of SEO, we have $N_i[v_k] \subseteq N_i[v_j]$ and hence using Lemma 4.1, we note that $D' = (D \setminus \{v_k\}) \cup \{v_j\}$ is a dominating set of G such that $|D'| = |D|$. Now in order to prove that D' is a semi-TD-set, we need to prove the following claim.

Claim 4.1. *For all $v_l \in N_G^2(v_k) \cap D$, there exists a vertex $v_r \in D'$ such that $d_G(v_l, v_r) \leq 2$ and there exists a vertex $u \in N_G^2(v_j) \cap D'$.*

Proof : From previous arguments we note that $i \leq k < j$. Also $v_i v_k, v_k v_j, v_i v_j \in E(G)$. Let $v_l \in N_G^2(v_k) \cap D$ be an arbitrary vertex. If $(N_G^2(v_l) \cap D) \setminus \{v_k\} \neq \emptyset$, that is, there is a vertex u other than v_k in D such that $d_G(v_l, u) \leq 2$, then the result follows. Hence, we assume that $N_G^2(v_l) \cap D = \{v_k\}$.

If $v_l v_k \in E(G)$ then we note that $d_G(v_l, v_j) \leq 2$ as $v_k v_j \in E(G)$, and the result follows. Assume that $d_G(v_k, v_l) = 2$. Let $v_l v_{l'} v_k$ be any shortest path between v_l and v_k in G . If $l' \geq i$ then using the property SEO, we have $v_{l'} v_j \in E(G)$, implying that $d_G(v_l, v_j) \leq 2$, hence the result follows.

Now suppose, $l' < i$. We have $v_{l'} v_l, v_{l'} v_k \in E(G)$. Therefore, if $l' < l$, then using property of SEO, $v_l v_k \in E(G)$, contradicting the assumption that $d_G(v_k, v_l) = 2$. Hence, we have $l < l' < k$. Further, using Lemma 3.4, we note that if v_l has a neighbour v_s such that $s \geq i$, then $d_G(v_l, v_j) \leq 2$. Hence, the result follows. Suppose, v_l has no neighbour v_s such that $s \geq i$. In this case, we show that either the vertex v_l already has a distance two neighbour in D or we can remove v_l to get a semi-TD-set of smaller cardinality.

Here, first we show that there exists a vertex $v_{a'} \in D$ such that $a' \neq k$ and $d_G(v_j, v_{a'}) \leq 2$. We have $v_{l'} v_k \in E(G)$ and since $l' < i$, $D(v_{l'}) = 1$. We note that, $N_i[v_j] \not\subseteq N_i[v_k]$ as if $N_i[v_j] \subseteq N_i[v_k]$ then $v_k \in B_i[v_i]$, a contradiction. Hence, we have a vertex $v_a \in N_i[v_j]$ such that $v_a v_k \notin E(G)$ that is, v_a can not be dominated by v_k . Hence, there exists a vertex $v_{a'} \in D \setminus \{v_k\} \subseteq D'$ such that $v_a v_{a'} \in E(G)$. Therefore, we have a vertex $v_{a'} \in D \setminus \{v_k\} \subseteq D'$ such that $d_G(v_{a'}, v_j) \leq 2$.

Now, suppose $v_l \notin D_{i-1}$. Using Lemma 4.1 and the fact that v_l has no neighbour v_s such that $s \geq i$, the set $D'' = D' \setminus \{v_l\}$ is a semi-TD-set of G such that $|D''| < |D|$, a contradiction as D is a minimum semi-TD-set of G . If $v_l \in D_{i-1}$ and $L(v_l) = 1$ then by Lemma 4.1, there is a neighbour of v_l having index greater than i which is marked for v_l , a contradiction as v_l has no neighbour having index greater than i . If $v_l \in D_{i-1}$ and $L(v_l) = 2$, then there exists a vertex $v \in D_{i-1}$ such that $d_G(v_l, v) \leq 2$. Also we have a vertex $v_{a'} \in D'$ such that $d_G(v_j, v_{a'}) \leq 2$ and hence, the claim follows. \square

Consequently, in this case the result follows. Now we consider the other case.

Case 2: If $v_k \neq v_l$

Since we have $D(v_i) = 0$, $v_k \notin D_{i-1}$. If $k \geq i$, then using property of SEO, we note that $N_i[v_k] \subseteq N_i[v_j]$. Also if $k < i$, then $N_k[v_k] \subseteq N_k[v_i]$ implying that $N_i[v_k] \subseteq N_i[v_i] \subseteq N_i[v_j]$. Hence, the set $D' = D \setminus \{v_k\} \cup \{v_j\}$ is a dominating set of G . Also as v_j is dominated by v_l in D and $v_l \in D \setminus \{v_k\} \subseteq D'$ hence, for $v_j \in D'$ we have $v_l \in D'$ such that $d_G(v_j, v_l) \leq 2$. Consequently, to prove D' is a semi-TD-set of G we need to prove the following claim.

Claim 4.2. *For any vertex $v_r \in N_G^2(v_k)$, there exists a vertex u such that $d_G(v_r, u) \leq 2$.*

Proof : Let $v_r \in N_G^2(v_k) \cap D$ be an arbitrary vertex. Note that if there exists a vertex $x \in (N_G^2(v_r) \cap D) \setminus \{v_k\}$ then the result follows. Hence we assume that $N_G^2(v_r) \cap D = \{v_k\}$. If $k \geq i$, then we can give similar arguments as we gave in Claim 4.1, to show that there exists a vertex $v_s \in D'$ such that

$d_G(v_r, v_s) \leq 2$ and hence, the result follows. Let $k < i$. First assume that $r > k$. As $v_k v_i \in E(G)$, $k < i$, and $v_j = F(v_i)$, using Lemma 3.3, we have $N_k^2[v_k] \subseteq N_k^2[v_j]$. Therefore in this case, $d_G(v_r, v_j) \leq 2$ and the claim follows.

Now suppose, $r < k$. In this case, if $v_r v_k \in E(G)$ and v_r has a neighbour v_s such that $s > i$ then using Lemma 3.6, we have $d_G(v_r, v_j) \leq 2$. Now, assume that $d_G(v_r, v_k) = 2$ and $P = v_r v_{r'} v_k$ be a shortest path joining v_r and v_k . Note that $r' > r$, otherwise using the property of SEO, we have $v_r v_k \in E(G)$. Now if v_r has a neighbour v_s such that $s > i$ then using Lemma 3.6, again we have, $d_G(v_r, v_j) \leq 2$ and we are done.

Suppose v_r does not any neighbour v_s such that $s > i$. Note that if $v_r \in D_{i-1}$ then $L(v_r) = 2$. Indeed, if $L(v_r) = 2$ then by Lemma 4.1, there exist a neighbour v_s of v_r such that $s \geq i$ and $m(v_s) = r$. Since, v_r has no neighbour having index greater than i , we have a contradiction. Further, if $v_l \notin D_{i-1}$, then using Lemma 4.1 and the fact that v_l has no neighbour having index greater than i , the set $D'' = D' \setminus \{v_l\}$ is a semi-TD-set of G such that $|D''| < |D|$, a contradiction, as D is a minimum semi-TD-set of G . Hence, the claim follows. \square

As the lemma follows in both the cases, therefore, the result follows. \square

Lemma 4.4. *If $D(v_i) = 0$, $F(v_i) \neq v_i$, and $v_k \in B_i[v_i] \neq \emptyset$ where $k = \max\{k' \mid v_{k'} \in B_i[v_i]\}$ then there exists a minimum semi-TD-set D' of G such that $(D_{i-1} \cup \{v_k\}) \subseteq D'$.*

Proof : If $v_k \in D$ then the result follows. Suppose $v_k \notin D$. Let $v_r \in D$ be the least index vertex dominating v_i . Since $D(v_i) = 0$, $v_r \notin D_{i-1}$. Note that if $r < i$, then using the property of SEO, we have $N_r[v_r] \subseteq N_r[v_i]$ and hence, $N_i[v_r] \subseteq N_i[v_i] \subseteq N_i[v_j] \subseteq N_i[v_k]$. Also, if $r > i$ then using the property of SEO, we have $N_i[v_r] \subseteq N_i[v_j] \subseteq N_i[v_k]$. Hence, using Lemma 4.1 and the fact that $N_i[v_r] \subseteq N_i[v_k]$, we note that the set $D' = (D \setminus \{v_r\}) \cup \{v_k\}$ is a dominating set of G . Further, we note that $v_k \in B_i[v_i]$. Hence, there exists a vertex $w \in N_G[v_k]$ such that $D(w) = 1$. Consequently, there exists a vertex $u \in N_G^2(v_k) \cap D_{i-1}$ such that $d_G(v_k, u) \leq 2$. Now to prove that D' is a semi-TD-set of G we need to prove the following claim:

Claim 4.3. *For any vertex $v_a \in N_G^2(v_r) \cap D'$, there exists a vertex $u \in D'$ such that $d_G(v_a, u) \leq 2$.*

Proof : If there exists a vertex $x \in (N_G^2(v_a) \cap D) \setminus \{v_r\}$ then the result follows. Hence we assume that $N_G^2(v_a) \cap D = \{v_r\}$.

Case 1: If $r \geq i$.

Since, $v_i v_r \in E(G)$ and $r \geq i$, the property of SEO implies, $N_i[v_r] \subseteq N_i[v_j]$. Now, using the fact that $v_k \in B_i[v_i]$, we have $N_i[v_r] \subseteq N_i[v_j] \subseteq N_i[v_k]$. Let $v_a \in N_G^2(v_r) \cap D'$ be an arbitrary vertex. Since, in this case, $v_r v_k \in E(G)$ therefore, if $v_a v_r \in E(G)$, then we have $d_G(v_a, v_k) \leq 2$ and result follows. So for further cases, we assume that $d_G(v_a, v_r) = 2$ and $P = v_a v_{a'} v_r$ is a shortest path between v_a and v_r in G .

Suppose $a \geq i$. Since $a, r \geq i$, we have $a' > i$. Indeed if $a' < i$ then using property of SEO, we observe that, $v_a v_r \in E(G)$, a contradiction to our assumption that $d_G(v_a, v_r) = 2$. Further, in this case, using the fact that $N_i[v_r] \subseteq N_i[v_k]$, we have $v_{a'} v_k \in E(G)$. This implies that $d_G(v_a, v_k) \leq 2$ and hence, the result follows.

Now suppose, $a < i$. Note that if $a' > i$ then using the the fact that $N_i[v_r] \subseteq N_i[v_k]$, we have $v_{a'} v_k \in E(G)$. Hence we have, $d_G(v_a, v_k) \leq 2$ and the result follows. Now, assume that $a' < i$. In that case, we have $a < a'$. Indeed, if $a' > a$ then using property of SEO, we have $v_a v_r \in E(G)$, a contradiction. Now if v_a has a neighbour v_s such that $s \geq i$, then suing property of SEO, $v_{a'} v_s, v_r v_s \in E(G)$. Indeed we have $v_s v_k \in E(G)$, hence, $d_G(v_k, v_a) \leq 2$. Now suppose v_a has no neighbour v_s such that $s \geq i$. Here, if $v_a \in D_{i-1}$ then $L(v_a) = 2$ as if $L(v_a) = 1$, then by Lemma 4.1, there exists a vertex v_s where

$s \geq i$ such that $v_a v_s \in E(G)$ and $m(v_s) = a$, a contradiction. If $v_a \notin D_{i-1}$ then as v_a has no neighbour having index greater than i , we note that the set $D'' = D' \setminus \{v_a\}$ is a semi-TD-set of G , contradicting the choice of D . And hence the claim follows.

Case 2: If $r < i$.

First suppose $a \geq i$. If $v_a v_r \in E(G)$, then using the property of SEO, we note that $d_G(v_k, v_a) \leq 2$. Suppose, $d_G(v_a, v_r) = 2$, and $P = v_a v_{a'} v_r$ is a shortest path between v_a and v_r in G . Note that, if $a' < r$, then we have $v_r v_a \in E(G)$, contradiction to our assumption that $d_G(v_k, v_a) \leq 2$. Hence, $r' > k$. Also we have $v_r v_i \in E(G)$ therefore using property of SEO we have, $N_r[v_r] \subseteq N_r[v_i]$. If $a' < i$, then we have $v_i v_{a'} \in E(G)$ and $N_{a'}[v_{a'}] \subseteq N_{a'}[v_i]$, implying that $d_G(v_a, v_k) \leq 2$. Otherwise, we have $v_i v_{a'} \in E(G)$ with $a' > i$, implying, $v_k v_{a'} \in E(G)$, and hence, $d_G(v_a, v_k) \leq 2$. Therefore, in this case, the result follows.

Now, suppose $a < i$. If v_a does not have a neighbour having index greater than i then using Lemma 4.1, either $L(v_a) = 2$ or $v_a \notin D_{i-1}$. In the former case we note that the set $D'' = D' \setminus \{v_a\}$ is a semi-TD-set of G , contradicting the choice of D . If v_a has a neighbour having index greater than i , then as we discussed in previous cases, using the property of SEO, we may observe that the $d_G(v_k, v_a) \leq 2$. And hence the claim follows. \square

This proves the lemma. \square

Lemma 4.5. *If $D(v_i) = 0$ and $F(v_i) = v_i$ then there exists a minimum semi-TD-set D' of G such that $(D_{i-1} \cup \{v_i\}) \subseteq D'$.*

Proof : As $F(v_i) = v_i$, it follows from Lemma 3.5 that $i = n$. Since the graph is connected, there exists a neighbour v_r of v_n such that $r < n$. Also, using Lemma 4.1, we note that $D(v_j) = 1$ and $m(v_j) = 0$ for $j \in [n-1]$, implying that, $D(v_r) = 1$. Indeed, $m(v_n) = 0$ as if $m(v_n) = k \neq 0$, then $v_k \in D_{i-1}$. Also we have $v_k v_n \in E(G)$ hence, $D(v_n) \neq 0$, a contradiction. By induction hypothesis, we note that there exists a minimum semi-TD-set D such that $D_{n-1} \subseteq D$. Suppose, $v_l \in D$ is the least index vertex dominating v_n . Clearly, $v_l \notin D_{i-1}$. Using Lemma 4.1, we note that the set $D' = (D \setminus \{v_l\}) \cup \{v_n\}$ is a dominating set of G , such that $|D| = |D'|$. Now in order to show that D' is a semi-TD-set, we need to show that, for every vertex $v_k \in N_G^2(v_l) \cap D$ there exists a vertex u such that $d_G(v_k, u) \leq 2$.

If there exists a vertex $x \in (N_G^2(v_k) \cap D) \setminus \{v_l\}$, then the result follows. Hence we assume that $N_G^2(v_k) \cap D = \{v_l\}$. If $v_k \notin D_{n-1}$ then we may note that $D'' = D' \setminus \{v_k\}$ is a semi-TD-set of smaller cardinality, a contradiction. Further, if $v_l \in D_{n-1}$ and $L(v_l) = 1$ then by Lemma 4.1, there exists a vertex $v_{k'}$ such that $m(v_{k'}) = k$ and $k' \geq n$, a contradiction. If $v_l \in D_{n-1}$ and $L(v_l) = 2$, the result follows. This proves the lemma. \square

Lemma 4.6. *If $D(v_i) \neq 0$, $m(v_i) = s \neq 0$ and $F(v_s) = v_t$ then the following hold:*

1. *If $i < t$ then there is a vertex $v_r \in N[v_s]$ such that $m(v_r) = s$ and $r(\neq i) > i$.*
2. *If $i = t$ and $F(v_i) = v_i$ then there is a minimum semi-TD-set D' of G such that $(D_{i-1} \cup \{u\}) \subseteq D'$ where $u \in N_G[v_i]$.*
3. *If $i = t$ and $F(v_i) \neq v_i$ then there is a minimum semi-TD-set D' of G such that $(D_{i-1} \cup \{F(v_i)\}) \subseteq D'$.*

Proof : Let $D(v_i) \neq 0$, $m(v_i) = s \neq 0$ and $F(v_s) = v_t$ where $t \geq s$. First we will prove the following claims are true before the start of i^{th} -iteration.

Claim 4.4. *There is a vertex v_a such that $N_G[v_a] \cap D_{i-1} = \{v_s\}$, where $a < s$ and $F(v_a) = v_s$.*

Proof : Suppose v_s is selected in a^{th} -iteration of the algorithm. We note that the algorithm selects the vertex v_s in a^{th} -iteration only if $D(v_a) = 0$. Furthermore, the algorithm updates $L(v_s) = 1$ and performs the MARK(v_s) operation only if $B_a[v_a] = \emptyset$. Hence, before the start of a^{th} -iteration, we have $D(v_a) = 0$, $F(v_a) = v_s$ and $B_a[v_a] = \emptyset$. After the a^{th} -iteration the algorithm has selected v_s to dominate v_a and has performed MARK(v_s) operation. Hence, $v_s \in (N_G[v_a] \cap D_{i-1})$. Further, if $s = a$ then $F(v_a) = v_a = v_s$. In this case, in the a^{th} -iteration, the algorithm would have updated $L(v_s) = 2$, and no neighbour of v_s would have marked, a contradiction. Hence $a < s$.

Now suppose there is another vertex $v_c \in (N_G[v_a] \cap D_{i-1})$ such that $c \neq s$ and suppose v_c is selected in the b^{th} iteration. In the a^{th} iteration, we have $F(v_a) = v_s$ and $B_a[v_a] = \emptyset$. If $b < a$, that is, if v_c is selected before the start of a^{th} -iteration, then the algorithm would have updated $D(v_a) = 1$ in the b^{th} -iteration. This is a contradiction to the fact that $D(v_a) = 0$ in a^{th} iteration. Now suppose that $b > a$. In this case we have $c > a$ and $v_c v_s \in E(G)$. Note that in the a^{th} -iteration the algorithm would have selected the vertex v_s and have performed the MARK(v_s) operation. Also we note that, $v_c v_s \in E(G)$. Now, in the b^{th} -iteration, after selecting the vertex v_c , the algorithm finds a vertex $F(v_a) = v_s \in N_G[c]$ such that $m(v_s) = s$. Hence, algorithm would have updated $L(v_s) = 2$ and have performed the operation UNMARK(v_s), a contradiction. This proves the claim. \square

Claim 4.5. *There is no vertex $v_r \in D_{i-1}$ such that $d_G(v_r, v_s) \leq 2$*

Proof : On contrary, we assume that there exists a vertex $v_r \in D_{i-1}$ such that $d_G(v_r, v_s) \leq 2$. Let v_s and v_r were selected in the x^{th} and y^{th} iteration of the algorithm. First suppose, $x > y$. In this case, the algorithm selected v_r first and then v_s is selected. Since, $d_G(v_r, v_s) \leq 2$ either $v_r v_s \in E(G)$ or v_r and v_s have a common neighbour v_a in G . We note that after the execution of y^{th} iteration, the algorithm would have updated $D(v_a) = 1$. And since $v_s v_a \in E(G)$, during the execution of x^{th} -iteration, the algorithm would have updated $L(v_s) = 2$, a contradiction.

Now we consider the case when $x < y$. In this case, the algorithm first selects v_s to dominate v_x and then v_r to dominate v_y . Also note that since, $d_G(v_r, v_s) \leq 2$ either $v_r v_s \in E(G)$ or v_r and v_s have a common neighbour v_a in G . Suppose $r < s$. If $v_r v_s \in E(G)$, then while selecting the vertex v_r , the algorithm would have updated $L(v_s) = 2$, a contradiction. Now suppose $d_G(v_r, v_s) = 2$ and let v_a be the common neighbour of v_r and v_s . Note that if $a < r$ then using the property of SEO, we have $v_r v_s \in E(G)$, a contradiction. Hence $a > r$. Further as $L(v_s) = 1$, in the y^{th} -iteration we have, $D(v_a) = 1$ and $m(v_a) = s$. Hence, after the y^{th} -iteration, the algorithm would have updated $L(v_s) = 2$, and performed UNMARK(v_s) operation, a contradiction. This proves the claim. \square

Now we continue the proof of the lemma. From above two claims, we note that there exists a vertex v_a such that $N_G[v_a] \cap D_{i-1} = \{v_s\}$, where $a < s$ and $F(v_a) = v_s$. Also, there is no vertex $v_r \in D_{i-1}$ such that $d_G(v_r, v_s) \leq 2$. We note that $D(v_i) \neq \emptyset$. Also by Lemma 4.1, $D(v_j) = 1$ for all $j \in [i - 1]$. Further, there is atleast one vertex, specifically v_t , such that $m(v_t) = s$. Hence, if $i < t$, then the result follows.

Further, we will prove that the Lemma follows in other two cases as well. We note that, using induction hypothesis, we have a minimum semi-TD-set D of G such that $D_{i-1} \subseteq D$. Furthermore, $L(v_s) = 1$ implies $v_s \in D_{i-1} \subseteq D$. As D is a minimum semi-TD-set of G , there exists another vertex $v_k \in D$ such that $d_G(v_s, v_k) \leq 2$. Using Claim 4.5, we note that $v_k \notin D_{i-1}$.

Now, first suppose $i = t$ and $F(v_i) = v_i$. We claim that there exists a minimum semi-TD-set of G containing $D_{i-1} \cup \{u\}$ where $u \in N_G[v_i]$. Note that $F(v_i) = v_i$ implies $i = n$. Therefore, using Lemma 4.1 and the fact that $D(v_i) = 1$, we note that the set $D' = (D \setminus \{v_k\}) \cup \{u\}$ is a minimum semi-TD-set of G where $u \in N_G[v_i]$.

Finally, suppose $i = t$ and $F(v_i) \neq v_i$. Now we need to show that there exists a minimum semi-TD-set containing $D_{i-1} \cup \{F(v_i)\}$. In this case, if $k < s$ then using Lemma 3.6, we have $N_i[v_k] \subseteq N_i[F(v_i)]$. Further, if $k > s$ then using Lemma 3.1, we have $v_k \in N_s[v_i]$, and hence, $N_i[v_k] \subseteq N_i[F(v_i)]$. Therefore, in all the above cases, we have $N_i[v_k] \subseteq N_i[F(v_i)]$. Hence, the set $D' = D \setminus \{v_k\} \cup \{F(v_i)\}$ is a dominating set of G . Let $F(v_i) = v_j$. In order to show that D' is a semi-TD-set of G , we need to prove the following claim.

Claim 4.6. *For every vertex $v_r \in N_G^2(v_k) \cap D'$, there exists a vertex $u \in D'$ such that $d_G(v_r, u) \leq 2$.*

Proof : Let $v_r \in N_G^2(v_k) \cap D'$ be an arbitrary vertex. Here $N_G^2(v_r) \cap D = \{v_k\}$. Indeed, if there is a vertex u such that $u \in (N_G^2(v_r) \cap D) \setminus \{v_k\}$ such that $d_G(v_r, u) \leq 2$ then the result follows. We will prove the claim by considering the following two cases:

Case 1: If $k < s$.

Note that the result follows if any of the three condition holds for a vertex $v_r \in N_G^2(v_k) \cap D'$: (i) $d_G(v_r, v_j) \leq 2$, (ii) $d_G(v_r, v_s) \leq 2$, and (iii) $v_r \in D_{i-1}$ and $L(v_r) = 2$. Suppose none of the three conditions hold for the vertex v_r . We need to consider the following two sub-cases:

Case 1.1: If $v_k v_s \in E(G)$.

In this case, using Lemma 3.2, we note that, $N_k^2[v_k] \subseteq N_k^2[v_s]$. Hence, if $r > k$ then we have $d_G(v_s, v_r) \leq 2$, a contradiction. Suppose $r < k$. If $v_r v_k \in E(G)$ then $d_G(v_s, v_r) \leq 2$, a contradiction. Next, assume that $d_G(v_k, v_r) = 2$. Let $v_r v_{k'} v_k$ be a shortest path between v_r and v_k in G . Note that $k' > r$, otherwise using the property of SEO, we have $v_r v_k \in E(G)$, a contradiction. Further, we note that if v_r has a neighbour $v_{r'}$ such that $r' \geq s$, then using Lemma 3.6, we have, $d_G(v_s, v_r) \leq 2$. By our assumption, if $v_r \in D_{i-1}$ then $L(v_r) = 1$, and by Lemma 4.1, there exists a neighbour $v_{r'}$ of v_r such that $r' \geq i \geq s$, implying that $d_G(v_s, v_r) \leq 2$, a contradiction. Therefore, $v_r \notin D_{i-1}$. Hence, using Lemma 4.1, and the fact that $v_r \notin D_{i-1}$, the set $D'' = D' \setminus \{v_r\}$ is a semi-TD-set of smaller cardinality, a contradiction.

Case 1.2: If $d_G(v_k, v_s) = 2$.

Let $v_k v_{k'} v_s$ be a shortest path between v_k and v_s in G . Here, if $k' < k$, then using the property of SEO, we have $v_k v_s \in E(G)$, a contradiction to our assumption that $d_G(v_k, v_s) = 2$. Hence, $k' > k$.

Case 1.2.1: If $r > k$.

As we have $v_k v_{k'} \in E(G)$ and $k < k'$, hence using Lemma 3.2, $N_k^2[v_k] \subseteq N_{k'}^2[v_{k'}]$. Consequently, $v_r \in N_k^2[v_k]$ implies $v_r \in N_{k'}^2[v_{k'}]$. If $v_r v_{k'} \in E(G)$, then we have $d_G(v_s, v_r) \leq 2$, a contradiction. Now, suppose $d_G(v_{k'}, v_r) = 2$ and $P = v_{k'} v_{r'} v_r$ be a shortest path between $v_{k'}$ and v_r .

If $k' > s$, using property of SEO, we have $v_{k'} v_i \in E(G)$. Since, $F(v_s) = v_i = v_t$, $k' < i$. Also if $r' \geq i$, then using property of SEO, we have $v_{r'} v_j \in E(G)$. This implies, $d_G(v_j, v_r) \leq 2$, a contradiction. Hence, $r' < i$. Now we consider the following two cases: (i) $r > k'$ and (ii) $r < k'$. In the first case, we note that $r' > k'$ and hence $v_{r'} v_i \in E(G)$. Since, we have $r > k'$, $v_{k'} v_i, v_{r'} v_i \in E(G)$, using the property of SEO we have, $v_r v_i \in E(G)$ and hence $d_G(v_r, v_j) \leq 2$, a contradiction.

Now, consider the second case, $r < k'$. In this case, we may note that, if v_r has a neighbour v_a such that $a \geq i$, then using Lemma 3.6, we have $d_G(v_j, v_r) \leq 2$, contradiction. Otherwise, using Lemma 4.1 and the fact that v_r has no neighbour v_a such that $a \geq i$, the set $D'' = D' \setminus \{v_r\}$ is a minimum semi-TD-set of smaller cardinality, a contradiction.

Now, consider the case if $k' \leq s$. Since, $v_{k'} v_s \in E(G)$, using Lemma 3.2, we have $N_{k'}^2[v_{k'}] \subseteq N_{k'}^2[v_s]$. Therefore, if $r > k'$, then we have $d_G(v_r, v_s) \leq 2$, a contradiction. Suppose $r < k'$. We note that if v_r has a neighbour v_a such that $a \geq i$, then using Lemma 3.6, we have $d_G(v_s, v_r) \leq 2$,

contradiction. Otherwise, using Lemma 4.1 and the fact that v_r has no neighbour v_a such that $a \geq i$, the set $D'' = D' \setminus \{v_r\}$ is a minimum semi-TD-set of smaller cardinality, a contradiction.

Case 1.2.2: If $r < k$.

If $v_k v_r \in E(G)$ and v_r has a neighbour $v_{r'}$ such that $r' > i$, then using Lemma 3.6, we have, $d_G(v_j, v_r) \leq 2$, a contradiction. Let $d_G(v_k, v_r) = 2$ and $P = v_k v_{r'} v_r$ be a shortest path joining v_k and v_r . Note that, $r' > r$. Here, if v_r has a neighbour v_a such that $a > i$, then using Lemma 3.6, we have, $d_G(v_j, v_r) \leq 2$, a contradiction. Hence, in any case we may assume that, v_r has no neighbour $v_{r'}$ such that $r' > i$. Consequently, using Lemma 4.1 and the fact that v_r has no neighbour v_a such that $a \geq i$, the set $D'' = D' \setminus \{v_r\}$ is a minimum semi-TD-set of smaller cardinality, a contradiction. Hence, the result follows.

Case 2: If $k > s$.

Since, $v_s v_i \in E(G)$ such that $s < i$ and $F(v_s) = v_t = v_i$, using Lemma 3.1, we have $N_s^2[v_s] \subseteq N_s[v_i]$. Hence, $v_k v_i \in E(G)$.

Case 2.1: If $k < i$.

In this case, first suppose $r > k$. If $v_k v_r \in E(G)$, then using the property of SEO, we have $v_r v_i \in E(G)$ and $d_G(v_k, v_j) \leq 2$, a contradiction. Now, assume that $d_G(v_k, v_r) = 2$ and $P = v_k v_a v_r$ be a shortest path between v_k and v_r in G . Note that if $a < k$, then using the property of SEO, we have, $v_k v_r \in E(G)$, a contradiction. Hence, $a > k$. If $a > i$, then using the property of SEO, we have $v_a v_i \in E(G)$ and hence, $v_a v_j \in E(G)$. Therefore, $d_G(v_k, v_j) \leq 2$, a contradiction. Now if $a < i$, then using the property of SEO, we have $v_a v_i \in E(G)$. Further, as $r > k$ and $v_a v_r \in E(G)$, hence using the property of SEO, $v_i v_r \in E(G)$, implying that $\rightarrow d_G(v_k, v_j) \leq 2$, a contradiction.

Next, suppose $r < k$. If $v_k v_r \in E(G)$ and v_r has a neighbour $v_{r'}$ such that $r' \geq i$ then using Lemma 3.6, we have $d_G(v_r, v_j) \leq 2$, a contradiction. Now we consider the case if $d_G(v_k, v_r) = 2$. Let $v_r v_{k'} v_k$ be any shortest path between v_k and v_k in G . Here also, we observe that if v_r has a neighbour $v_{r'}$ such that $r' \geq i$ then using Lemma 3.6, we have $d_G(v_r, v_j) \leq 2$, a contradiction. Hence, in both cases, v_r has no neighbour $v_{r'}$ such that $r' \geq i$. Consequently, using this fact and Lemma 4.1 we note that the set $D'' = D' \setminus \{v_r\}$ is a semi-TD-set of smaller cardinality, a contradiction. Hence, the result follows.

Case 2.2: If $k \geq i$.

Using Lemma 3.4, we note that $N_i^2[v_k] \subseteq N_i^2[v_j]$. Hence, if $r > i$ then $d_G(v_j, v_r) \leq 2$, a contradiction. Now consider the case when $r < i$. Similar to the previous cases, we note that if v_r has neighbour having index greater than i then $d_G(v_r, v_j) \leq 2$, a contradiction. Further, if v_r has no neighbour having index greater than i , then using Lemma 4.1 we note that, the set $D'' = D \setminus \{v_r\}$ is a semi-TD-set of smaller cardinality, a contradiction. Hence, the result follows. \square

This proves the lemma. \square

Using Lemma 4.1 to Lemma 4.6, we may conclude that the set D_n is a minimum semi-TD-set of G . Further, we may note that the Algorithm 1 can be implemented in linear-time. Hence, we have the following result.

Theorem 4.1. *Given a strongly chordal graph $G = (V, E)$, with strong elimination ordering α of vertex set V , a minimum semi-TD-set of G can be computed in linear time.*

5 Conclusion

In this paper, we resolved the complexity status of MINIMUM SEMITOTAL DOMINATION problem in strongly chordal graph, which is an important subclass of chordal graphs. The complexity status of the problem in dually chordal graphs and tolerance graphs is still unknown. It would be interesting to investigate the complexity of the problem in these graph classes. Further, as the problem is NP-complete in planar graphs, designing approximation algorithms for the problem in planar graphs is a good research direction.
