## Abstract

Recently, deep network-based image compressed sensing methods achieved high reconstruction quality and reduced computational overhead compared with traditional methods. However, existing methods obtain measurements only from partial features in the network and use them only once for image reconstruction. They ignore there are low, mid, and high-level features in the network [38] and all of them are essential for high-quality reconstruction. Moreover, using measurements only once may not be enough for extracting richer information from measurements. To address these issues, we propose a novel Measurements Reuse Convolutional Compressed Sensing Network (MR-CCSNet) which employs Global Sensing Module (GSM) to collect all level features for achieving an efficient sensing and Measurements Reuse Block (MRB) to reuse measurements multiple times on multi-scale. Finally, experimental results on three benchmark datasets show that our model can significantly outperform state-of-the-art methods. Code is available at: <https://github.com/fze0012/MR-CCSNet>.

## 1. Introduction

Compressed Sensing [11](CS), a signal processing technique, can efficiently acquire and reconstruct a signal. It has developed rapidly and attracted the attention of many researchers. Given a high-dimensional signal  $x \in \mathbb{R}^N$ , we get the measurements of  $x$ , denoted by  $y \in \mathbb{R}^M$ , by a linear mapping  $y = \Phi x$ , where  $\Phi \in \mathbb{R}^{M \times N}$  is sensing matrix and  $\frac{M}{N}$  is sampling ratio. Because  $M \ll N$ , recovering  $x$  is generally impossible for the ill-posed problem. CS shows that the original signal  $x$  can be recovered from  $y$  with high probability when the signal  $x$  is sparse in some domain [6, 12].

The two core problems of image CS are (1) the design of sensing matrix and (2) recovering the high-dimensional signal  $x$  from its low-dimensional measurements  $y$ . For the

former one, many matrices [1, 10, 15, 16, 25] are proposed, but they are hand-designed and ignore there are statistical correlation between different elements of signal. For the latter one, the papers of [7, 23, 30, 41, 42] propose methods for exploring image priors and combining optimization criteria and iterative thresholding algorithms [17]. These methods require high computational overhead and perform poorly when the sampling ratio is extremely low.

In recent years, deep learning has been widely used in computer vision and shows superior performance [21, 24]. Researchers were inspired to solve these two challenges of CS with deep learning, called Deep Compressed Sensing (DCS). A few DCS methods [27, 28, 32, 34, 40] have been proposed and achieve promising results since the powerful learning and representation capabilities of neural networks.

Despite their success, existing DCS methods only use a convolutional layer to learn the sensing matrix, which ignores the spatial features in the image. In addition, because the residual architecture is widely used in reconstruction network, the reconstruction quality relies on it. To address these issues, Zheng *et al.* proposed RK-CCSNet [43]. For the former one, RK-CCSNet use the Sequential Convolutional Module (SCM) to gradually compact the image size through a sequence of filters. For the latter one, RK-CCSNet proposed the second-order residual architecture according to the relationship between ResNet [18] and Ordinary Differential Equation.

Although RK-CCSNet proposed an effective strategy for image CS, it always suffers from these problems: (1) There are hierarchical nature of the features in the convolutional neural networks (CNNs): the low, mid, and high layer learn features such as edges, complex textures, and objects, respectively. But RK-CCSNet only samples from the highest layer, which ignores a large amount of rich features contained in those neglected layers; (2) Existing methods [27, 32, 40, 43] recover the original image from measurements using deep learning, which takes measurements as input and use it only once. It extracts features from measurements in a rather shallow manner.

To address these issues, we propose Global Sensing Module (GSM) and Measurements Reuse Block (MRB). In

\*Corresponding author.

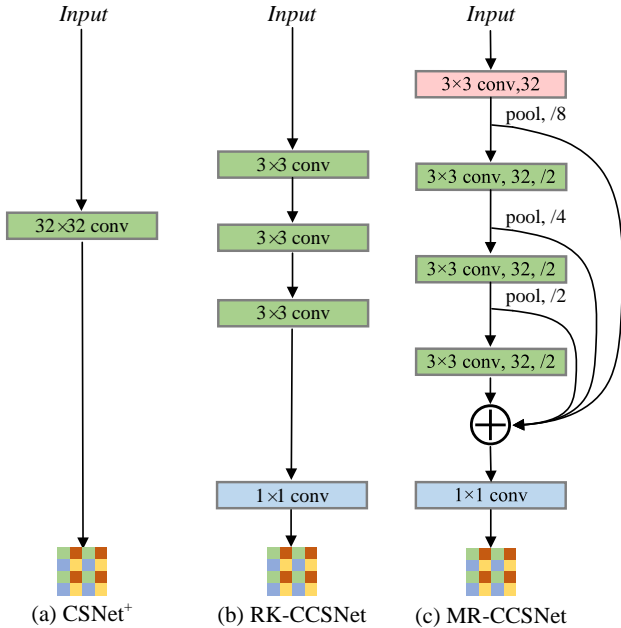

Figure 1. This figure shows the sensing network of CSNet<sup>+</sup> [32], RK-CCSNet [43], and our proposed model. (a): There is only a convolutional layer, so the spatial features in the image are ignored. (b): Although there are multiple convolutional layers, it only samples from the highest layer. Therefore, there are the highest level features in the measurements and low and mid-level features are ignored. (c) Overview of GSM. To take advantage of the hierarchical nature of the CNNs, which are neglected in RK-CCSNet, we use a shortcut connection pass the features of different layer to the end. And then,  $1 \times 1$  convolutions are used to sample. Because we sample from all level features, there are richer features in measurements than CSNet<sup>+</sup> and RK-CCSNet.

GSM, as shown in Fig. 1, we first use a convolutional layer to get a high dimensional feature. After that, we gradually compact the feature maps by multiple convolutional layers. And then we collect all level features in the network. Finally, we obtain measurements by  $1 \times 1$  convolutions. In order to match dimensions, we add pooling layer into the shortcut connection. In MRB, we first compact the phased reconstructed result and get multiple feature maps. After that, we extract matching information from measurements. Finally, we fuse them on multi-scale. It is a promising manner to move from shallow measurements utilizing to deep.

We conduct experiments on three benchmark data sets: BSDS500 [2], Set5 [4], and Set14 [39] and chose PSNR and SSIM [19] as the evaluation metrics. Evaluation results indicate that MR-CCSNet can significantly outperform state-of-the-art methods. In particular, we show that our model can achieve high reconstruction quality at low sampling ratio. In addition, we show that GSM and MRB are effective by ablation studies.

To conclude, our contributions are three-fold: (1) pro-

posal of the GSM which can achieve efficient sampling; (2) proposal of the MRB for making full use of measurements; (3) building an end-to-end network MR-CCSNet for image CS based on GSM and MRB, and demonstrating its effectiveness on three benchmark data sets.

## 2. Related work

CS aims to recover the original signal  $x$  from its limited measurements  $y$ . We will review some of existing works from two categories:

**Traditional Compressed Sensing** Traditional CS methods regard the signal reconstruction as an optimization problem. The objective function of this optimization problem is

$$\min_x \frac{1}{2} \|\Phi x - y\|_2^2 + \lambda \|Dx\|_1, \quad (1)$$

where  $D$  is a projection operators (wavelet or DCT).  $\ell_1$  norm controls the sparsity of  $Dx$ .

The convex optimization methods [8], the greedy algorithms [26, 35], and the gradient descent methods [9, 13, 36] are three representative methods. For image compressed sensing, many researchers introduce other prior as a regularization item. In [23], in order to improve the smoothness, Li *et al.* used the total variation (TV) regularized constraint. In [41], Zhang *et al.* proposed group sparse representation (GSR), which sparsely represented images in the domain of group and enforced the local sparsity and nonlocal self-similarity. Furthermore, the projected Landweber (PL) algorithm [3] was introduced to image CS. In [15], Gan proposed block-based CS based Wiener filtering PL iteration. In recent years, researchers have also proposed many improved PL-based methods [7, 14, 31]. Besides image reconstruction methods, some attention is also paid to the sensing matrix. In most works, the sensing matrix is a random Gaussian matrix, which satisfies the Restricted Isometry Property (RIP) [5] with high probability. Although so many methods have been proposed in traditional CS, they all require a lot of computing resources and perform poorly when the sampling ratio is extremely low.

**Deep Compressed Sensing** The main idea of DCS is to learn the mapping from the measurements to the original signal using a neural network, so the speed and accuracy of reconstruction are improved. Generally, we train the network by minimizing the loss function

$$\min_{\theta} \frac{1}{2} \sum_{n=1}^N \|x_n - F(y_n, \theta)\|_2^2, \quad (2)$$

where the  $x_n$  is the original image,  $y_n$  is the measurements of  $x_n$ , and  $F$  is the neural network parameterized by  $\theta$ . Many DCS methods have been proposed [22, 27, 29, 32, 33,

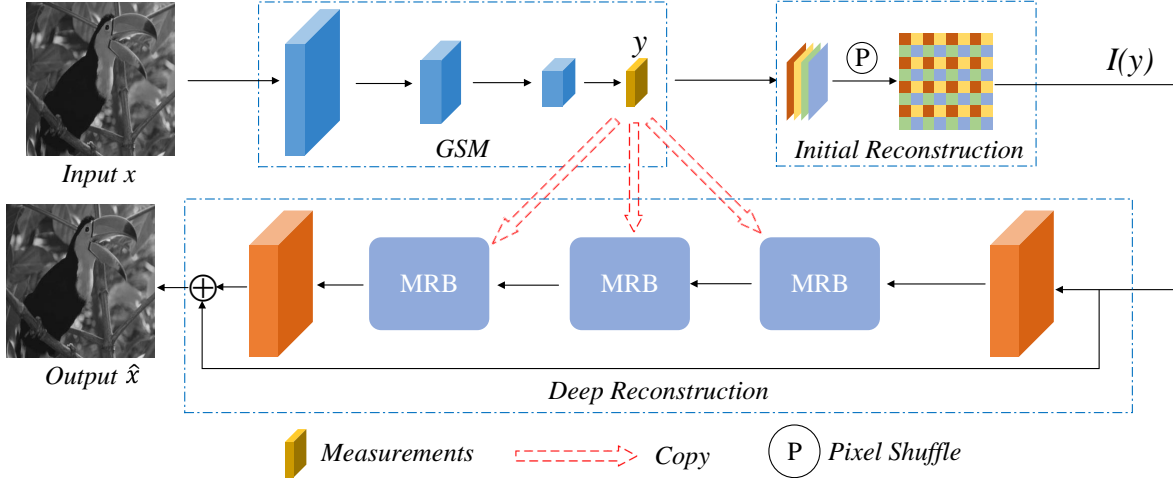

Figure 2. Overview of the proposed model. For the original image  $x$ , we obtain measurements  $y$  from the sensing network GSM. And then the initial reconstructed image  $I(y)$  is generated by the initial reconstruction network. Finally, we refine the  $I(y)$  by the deep reconstruction network.

[43]. In [29], Mousavi *et al.* proposed a stacked denoising autoencoder (SDA) to learn a structured representation from training data. However, SDA has the computational complexity because it used many full connection layers. In [22], Kulkarni *et al.* introduced ReconNet, which used CNN to reduce the number of model parameters by weight sharing. Mousavi and Baraniuk [27] argued that real world signals are not exactly sparse on a fixed basis and the recovery algorithms take a lot of time to converge. And they proposed DeepInverse which learns both an effective representation for the signals and an inverse map. Shi *et al.* [32] argued that these methods ignore the characteristics of signal and proposed an end-to-end model CSNet<sup>+</sup> which uses convolutional neural network in sampling and reconstruction stage. However, when the sampling ratios change, these methods needed to train the model again, which is difficult to deploy for practical applications. Hence, Shi *et al.* [33] attempted to solve this problem with greedy method and proposed SCSNet. Mousavi *et al.* [28] proposed DeepSSRR which employs a parallelization scheme in the signal sensing and recovery process to accelerate the convergence speed. In [43], Zheng argued that existing end-to-end methods do not preserve the spatial features in the image and proposed RK-CCSNet, which applies Sequential Convolutional Module (SCM) to gradually compact measurements through a series of convolution filters. In addition, RK-CCSNet also proposed a novel Learned Runge-Kutta Block (LRKB) based on the famous Runge-Kutta methods for improving the reconstruction quality.

Our work is also inspired by the idea of multi-scale in image processing. In [37], Xu *et al.* proposed a Laplacian pyramid reconstructive adversarial network (LAPRAN) which reconstructs the original image through multiple

stages with different resolution simultaneously. Our model also employs MRB to fuse features learned from measurements on multi-scale.

### 3. Methodology

In this section, we will introduce our model in the case of sampling ratio is 6.25%. Fig. 2 shows the architecture of MR-CCSNet. Following CSNet<sup>+</sup> [32] and RK-CCSNet [43], MR-CCSNet has a sensing network GSM, an initial reconstruction network, and a deep reconstruction network. We denote them as  $S(\cdot)$ ,  $I(\cdot)$ ,  $D(\cdot)$ , respectively. Firstly, we obtain the measurements  $y$  from  $S(\cdot)$ . Then, we use a linear mapping  $I(\cdot)$  to generate initial reconstructed image  $I(y)$ . Because the quality of  $I(y)$  is not enough, we refine it by a non-linear network  $D(\cdot)$ . To move from shallow measurements utilizing to deep, we stack multiple MRBs in the deep reconstruction network.

In the sensing network  $S(\cdot)$ , we directly use convolutional layers for the whole images instead of dividing the images into non-overlapping block [32, 33, 43]. For satisfying the linear property, there is no bias and activation function in the network. This process can be written as:

$$y = S(x), \quad (3)$$

where  $x \in \mathbb{R}^{1 \times H \times W}$  and  $y \in \mathbb{R}^{4 \times \frac{H}{8} \times \frac{W}{8}}$ .

In  $I(\cdot)$ , the depth-wise convolution layer expands the measurements in channel dimension and the shape becomes  $64 \times \frac{H}{8} \times \frac{W}{8}$ . Then we get a  $1 \times H \times W$  tensor by a pixel shuffle layer. This is the first time to utilize the measurements.

In the deep reconstruction network  $D(\cdot)$ , we first convert the initial reconstructed  $I(y)$  image to a high dimensional

Figure 3. Comparison of the GSM and the GSM<sup>+</sup>. The GSM<sup>+</sup> is flexible and can be easily used at various sampling ratios by repeating the building block, which is marked with red dotted box.

feature by a convolutional layer. Then repeated MRBs, which share the same internal structure, are used to fuse them with matching features extracted from measurements  $y$  multiple times on multi-scale. This is the second time to utilize the measurements.

Finally, we use a convolutional layer to get the reconstructed image. In addition, we add a shortcut connection to the deep reconstruction network. The final reconstructed image  $\hat{x}$  can be written as:

$$\hat{x} = D(I(y)) + I(y) \quad (4)$$

Our model uses two novel modules, GSM and MRB. They are explained below.

### 3.1. Global Sensing Module

By analyzing existing methods, we argue that a good feature extraction network can help sample. In addition, we learn that convolutional neural networks extract features in a hierarchical manner which means layers close to the input to learn low-level features, like lines and simple textures, and layers deeper in the model to learn high-order features, like shapes or specific objects from [38]. Based on these two principles, our proposed method GSM, as shown in Fig. 3a, has two stages. In the first stage, we use  $3 \times 3$  convolution layers to extract features. In the second stage, we collect all level features in the network and use a  $1 \times 1$  convolution layer to sample, rather than only from the low features (*i.e.* CSNet<sup>+</sup>) or high features (*i.e.* RK-CCSNet).

In GSM, to collect all level features for sampling, we use a shortcut connection to pass the features of different layers

to the end, and the pooling layer is added for matching the dimensions.

When the sampling ratio changes, the GSM is not flexible for meeting the new requirements. Inspired by ResNet [18], we propose the GSM<sup>+</sup>, as shown in Fig. 3b. Different from GSM, we add a shortcut connection between two successive layers rather than add it from different layers to the end directly. The building block of GSM<sup>+</sup> is marked with red dotted box and defined as:

$$y_{t+1} = Conv(y_t) + P(y_t), \quad (5)$$

where  $Conv$  and  $P$  denote convolution layer and mean-pooling layer, respectively. The sampling ratio is controlled by the number of building block and the blue block, so it is flexible and can be easily used at various sampling ratios by repeating the building block.

In GSM<sup>+</sup>, we can observe that it collect all level features for sampling, which is equivalent to GSM, by an iterative manner. Furthermore, there are richer features than GSM at each layer, because the features from former layer are passed to the current layer by shortcut connections. In a way, it achieve a more efficient feature extraction. When the sampling ratio is 50%, there is only one building block in GSM<sup>+</sup>, so GSM<sup>+</sup> degenerate into GSM. As the sampling ratio decreases, GSM is a special form of GSM<sup>+</sup>.

In the CS theory, the measurements is obtained by a linear mapping. It is trivial that the convolution layer and the mean-pooling layer are linear mappings. So the building block is linear mapping. According to composition preserves linearity, the GSM<sup>+</sup> is a linear mapping.

### 3.2. Measurements Reuse Block

The measurements are used only once for image reconstruction, which is difficult to extract richer information from measurements. The goal of MRB is to explore a novel approach for making full use of measurements multiple times on multi-scale.

Fig. 4 illustrates the architecture of MRB. Phased reconstructed result  $f_t \in \mathbb{R}^{C \times H \times W}$  and measurements  $y \in \mathbb{R}^{C \times \frac{H}{4} \times \frac{W}{4}}$  are fed into MRB. We firstly use two convolutional layers, denoted as  $Conv_1$  and  $Conv_2$ , to obtain a compacted feature map  $f^\downarrow$  and  $f^\downarrow$ . This process can be written as:

$$f^\downarrow = Conv_1(f_t), \quad (6)$$

$$f^\downarrow = Conv_2(f^\downarrow), \quad (7)$$

where  $f^\downarrow \in \mathbb{R}^{C \times \frac{H}{2} \times \frac{W}{2}}$ ,  $f^\downarrow \in \mathbb{R}^{C \times \frac{H}{4} \times \frac{W}{4}}$ . To fuse them with measurements on multi-scale, we then extract matching information from measurements and obtain three feature maps  $y_1 \in \mathbb{R}^{C \times \frac{H}{4} \times \frac{W}{4}}$ ,  $y_2 \in \mathbb{R}^{C \times \frac{H}{2} \times \frac{W}{2}}$ , and  $y_3 \in \mathbb{R}^{C \times H \times W}$  by Multi-Scale Reusing, which is shown in Fig. 5. Next,  $y_1$  is added into the backbone network of

Figure 4. Overview of the proposed MRB.

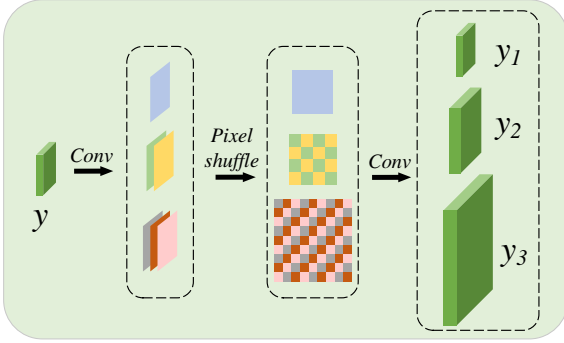

Figure 5. Overview of Multi-Scale Reusing. It aims to extract matching information for the backbone network of MRB.

MRB and obtain  $F_1$  by a concatenation operation and a convolutional layer. To preserve existing reconstruction results, we copy the  $f^{\downarrow}$  again and fuse them with  $F_1$  by a convolutional layer. Finally, a pixel shuffle layer is used to expand the fused feature map for next process. This process can be written as:

$$F_1 = \text{Conv}_3(f^{\downarrow} \oplus y_1), \quad (8)$$

$$f^{\uparrow} = \text{Pixel}(\text{Conv}_4(F_1 \oplus f^{\downarrow})), \quad (9)$$

where  $\oplus$  denotes a concatenation operation,  $y \in \mathbb{R}^{2 \times \frac{H}{4} \times \frac{W}{4}}$ ,  $y_1 \in \mathbb{R}^{C \times \frac{H}{4} \times \frac{W}{4}}$ ,  $F_1 \in \mathbb{R}^{C \times \frac{H}{4} \times \frac{W}{4}}$  and  $f^{\uparrow} \in \mathbb{R}^{C \times \frac{H}{2} \times \frac{W}{2}}$ . By repeating this process, phased reconstructed result measurements and measurements are fused at multi-scale. Then the output  $f_{t+1} \in \mathbb{R}^{C \times H \times W}$  is utilized as the input of next operation.

The MRB is not only a promising way for improving utilization of measurements, but also refines the phased reconstructed result at multi-scale.

### 3.3. Loss function

In the training phase, we use the mean square error to measure the reconstruction quality. Specifically, for the initial reconstruction network, the loss function can be written

as :

$$l_{int} = \sum_{k=1}^n \|I(S(y_k; \theta); \phi_{int}) - x_k\|_F^2. \quad (10)$$

For the deep reconstruction network, the loss function can be written as :

$$l_{deep} = \sum_{k=1}^n \|D(I(S(y_k; \theta); \phi_{int}); \phi_{deep}) - x_k\|_F^2, \quad (11)$$

where the  $\theta$ ,  $\phi_{int}$ , and  $\phi_{deep}$  denote the parameters of the sensing network  $S(\cdot)$ , the initial reconstructed network  $I(\cdot)$ , and the deep reconstructed network  $D(\cdot)$ , respectively. Therefore, we define a loss function of MR-CCSNet:

$$l = l_{deep} + l_{int}. \quad (12)$$

## 4. Experiments

### 4.1. Datasets and implementation details

Following RK-CCSNet [43], we use 400 images from BSDS500 [2] dataset to train our model. For testing, we report the performance on three standard benchmark datasets: Set5 [4], Set14 [39], and BSDS100 [2]<sup>1</sup>. We convert these images into YCbCr space and the Y channel is used as the input for training and testing. During training, in order to increase the number of samples, we randomly crop the image with patch size  $96 \times 96$ , and randomly flip horizontally. During testing, because the size of these images is inconsistent, we resize the image from Set5 and Set14 into  $256 \times 256$  and the image from BSDS100 into  $480 \times 320$ . To optimize our model, we use Adam optimizer [20] with  $\beta_1 = 0.9$ ,  $\beta_2 = 0.999$ . The batch size is set to 4 and our model is trained for 200 epochs. The initial learning rate is set to  $10^{-3}$  and reduced to quarter at 60, 90, 120, 150 and 180 epochs respectively. Six sampling ratios, *i.e.* 1.5625%, 3.1250%, 6.2500%, 12.5000%, 25.0000%, and 50.0000% are investigated. PSNR (Peak Signal-to-Noise Ratio) and

## 4.2. Comparison with the state-of-the-arts

To verify the effectiveness of MR-CCSNet and MR-CCSNet<sup>+</sup> where the sensing network is GSM and GSM<sup>+</sup> respectively, we quantitatively and visually compare them with 4 state-of-the-art methods with available codes, which is TVAL3 [23], GSR [41], CSNet<sup>+§</sup> [32], and RK-CCSNet<sup>§</sup> [43]<sup>2</sup>.

**Quantitative comparisons** In Tab. 1, we report the quantitative comparisons on Set5 and Set14. The results show that MR-CCSNet and MR-CCSNet<sup>+</sup> are outperforms the four methods at all sampling ratios. Note that all DCS methods show a significant improvement comparing with the best traditional method, *i.e.* GSR. Specifically, our model achieve the best performance in low sampling ratios. In average, MR-CCSNet<sup>+</sup> outperforms TVAL3, GSR, CSNet<sup>+§</sup>, and RK-CCSNet<sup>§</sup> by **9.94dB**, **3.89dB**, **1.58dB**, and **0.76dB** in terms of PSNR, respectively, on Set5 and Set14. In addition, the average SSIM of MR-CCSNet<sup>+</sup> can be im-

proved **0.2012**, **0.0916**, **0.0432**, and **0.0097**, respectively. We further compare MR-CCSNet and MR-CCSNet<sup>+</sup> with CSNet<sup>+§</sup> and RK-CCSNet<sup>§</sup> on BSDS100. Tab. 2 show the evaluation results. It can be seen that both MR-CCSNet and MR-CCSNet<sup>+</sup> achieve a better reconstruction quality at all sampling ratios. Especially in the case of sampling ratio of 1.5625%, MR-CCSNet<sup>+</sup> outperforms CSNet<sup>+§</sup> and RK-CCSNet<sup>§</sup> by **0.93dB** and **0.42dB**, respectively. Finally, we compare the performance of MR-CCSNet and MR-CCSNet<sup>+</sup>. When the sampling ratio is 50%, we observe that the PSNR and SSIM of them are very close. The reason is that GSM<sup>+</sup> degenerate into GSM in this case. As the sampling ratio decreases, MR-CCSNet<sup>+</sup> outperforms MR-CCSNet. The reason is that GSM<sup>+</sup> not only collects all level features, which is equivalent to GSM, but also extracts richer features for sampling and reconstructing. This is corresponding to our theoretical analysis in Sec. 3.1. All the experimental results demonstrate our model has state-of-the-art performance. **The more results are shown in Sec. 6.**

**Visual comparisons** We also visually compare our method with the state-of-the-art image CS methods. We magnify the results in order to compare the reconstruction

<sup>2</sup>§ means that we use the code provided in [43] to train this model.

Figure 6. Visual comparisons of reconstructed image on Woman from Set5 in the sampling ratio of 6.25%.

Figure 7. Visual comparisons of reconstructed image on Butterfly from Set5 in the sampling ratio of 12.5%.

details. Fig. 6 and Fig. 7 show the visual comparisons in the case of sampling ratio of 6.25% and 12.5%, respectively. We can see that DCS methods can achieve higher reconstruction quality than traditional methods in extremely low sampling ratios. In addition, our model also recover finer details than DCS methods CSNet<sup>+§</sup> and RK-CCSNet<sup>§</sup>. For example, in the figure of Butterfly and Woman, it is obvious that our model is able to reconstruct texture details, which is smoother and sharper than other methods. This is mainly because the measurements in our model contain all level features where the low and mid-level features relate to the edges and complex textures in the image. In addition, extracting richer features by utilizing measurements multiple times also plays an important role.

### 4.3. Running time comparison

In many practical applications, the running time is important and critical. Tab. 3 shows the average running time on GPU/CPU for reconstructing a 256×256 image. The re-

sults of TVAL3 and GSR are taken from [32], and they are implemented with an Intel Core i7-3770 CPU. The running times of CSNet<sup>+§</sup>, RK-CCSNet<sup>§</sup>, MR-CCSNet, and MR-CCSNet<sup>+</sup> are implemented with an Intel Core i9-9900k CPU and a Nvidia RTX 2080Ti GPU. It is obvious that tra-

Algorithm	sampling ratio=0.01		sampling ratio=0.1	
	CPU	GPU	CPU	GPU
TVAL3	2.3349	-	2.5871	-
GSR	235.6297	-	230.4755	-
CSNet <sup>+§</sup>	-	0.0075	-	0.0078
RK-CCSNet <sup>§</sup>	-	0.0184	-	0.0181
MR-CCSNet	-	0.0284	-	0.0272
MR-CCSNet <sup>+</sup>	-	0.0282	-	0.0271

Table 3. Average running time (in seconds).

ditional methods take about seconds to minutes to reconstruct the image. This is because they need multiple iterative operations during reconstruction. By comparison, the running time of DCS methods are improved by sev-

Figure 8. Visual comparisons of reconstructed image on Monarch from Set14 in the sampling ratio of 6.25%.

Table 4. The ablation studies of MR-CCSNet<sup>+</sup> on BSDS100.

eral orders of magnitude. The reason why our models slower than CSNet<sup>+</sup>§ and RK-CCSNet<sup>§</sup> is MR-CCSNet<sup>+</sup> has more parameters. But it is more fast compared with traditional methods and achieves better reconstruction quality. We can see that the running time of MR-CCSNet and MR-CCSNet<sup>+</sup> are equal. This is because two models have approximately the same number of parameters.

#### 4.4. Ablation studies

In order to verify the efficacy of GSM<sup>+</sup> and MRB, we further conduct ablation studies on BSDS100. The models compared include: Baseline (RK-CCSNet<sup>§</sup>), Baseline with GSM<sup>+</sup>, Baseline with MRB, and MR-CCSNet<sup>+</sup>. From the results, as shown in Tab. 4, we can observe that:

(1) Both GSM<sup>+</sup> and MRB are effective for improving the performance of reconstruction quality. This may be because GSM<sup>+</sup> can preserve more features in the image, and MRB can extract richer features for image reconstruction.

(2) When the sampling ratio is low, MRB plays a more important role than GSM<sup>+</sup> for image reconstruction. Alternatively, GSM<sup>+</sup> plays a more important role than MRB when the sampling ratio is 50%.

We also visually compare results of these four models, as shown in Fig. 8. The results is corresponding to our theoretical analysis. When the reconstruction algorithm is fixed, because GSM<sup>+</sup> takes advantage of the hierarchical nature of the network, the texture details of Baseline with GSM<sup>+</sup> smoother and sharper than Baseline. When the sensing network is fixed, because we utilize measurements in a deep manner, Baseline with MRB outperform Baseline.

## 5. Conclusion and future work

In this paper, we propose Global Sensing Module and Measurements Reuse Block for image CS. GSM can take advantage of the hierarchical nature of the network for sampling. MRB can make full use of the measurements for improving the reconstructed image quality. In the experiments, we show that our model significantly and consistently outperforms state-of-the-art image CS methods. In particular, our methods also have good performances in extremely low sampling ratios. In addition, we demonstrate that GSM and MRB are effective by ablation studies.

In the future, we will explore the following directions:

(1) In the sensing network, pooling operation loses information about the low-level features. We will explore a more effective way for collecting all level features.

(2) Attention mechanism can effectively help us in extracting matching features from measurements. We are interested in adding attention mechanism into MRB to improve its performance.

(3) In the real-world, because there are noise in the measurements, using them multiple times will introduce noise in the reconstruction process. We will explore how to improve the robustness for using measurements multiple times.
