

# Consistency is Key: Disentangling Label Variation in Natural Language Processing with Intra-Annotator Agreement

Gavin Abercrombie<sup>1</sup> and Verena Rieser<sup>1,2</sup> and Dirk Hovy<sup>3</sup>

<sup>1</sup>Heriot-Watt University, <sup>2</sup>Alana AI, <sup>3</sup>Bocconi University

## Abstract

We commonly use agreement measures to assess the utility of judgements made by human annotators in Natural Language Processing (NLP) tasks. While *inter*-annotator agreement is frequently used as an indication of label *reliability* by measuring consistency between annotators, we argue for the additional use of *intra*-annotator agreement to measure label *stability* over time. However, in a systematic review, we find that the latter is rarely reported in this field. Calculating these measures can act as important quality control and provide insights into *why* annotators disagree. We propose exploratory annotation experiments to investigate the relationships between these measures and perceptions of subjectivity and ambiguity in text items.

## 1 Introduction

Agreement measures are commonly used to assess the utility of judgements made by human annotators for Natural Language Processing (NLP) tasks. Indeed, the reporting of *inter*-annotator agreement (or inter-rater reliability) has long been the standard to indicate dataset quality (Carletta, 1996) and frequently serves as an upper bound for model performance on a task (Boguslav and Cohen, 2017).

While *inter*-annotator agreement is frequently used in NLP to determine the *reliability* of labels or the processes used to produce them (Artstein, 2017), *intra*-annotator agreement is rarely, if ever, reported. However, we can use it to measure the temporal consistency of the annotators who chose the labels and the *stability* of the labels. Consistency and label stability are important because, without them, annotation schemes are unlikely to be repeatable or reproducible (Teufel et al., 1999).<sup>1</sup>

Such measures of the *intra*-rater agreement are frequently reported in areas of medicine such as

physiotherapy (e.g. Bennell et al., 1998; Meseguer-Henarejos et al., 2018), and speech pathology (e.g. Capilouto et al., 2005; Rose and Douglas, 2003). *Intra*-rater measures are also reported in other fields as diverse as economics (Hodgson, 2008), software engineering (Grimstad and Jørgensen, 2007), and psychology (Ashton, 2000).

However, reporting *intra*-annotator agreement is so far extremely uncommon in NLP, as we show in the review in Section 2.

**Disagreement and label variation in NLP** In addition, we argue that the use of *inter*- and *intra*-annotator agreement allows us to distinguish and measure different sources of observed label variation (Rottger et al., 2022; Plank, 2022). This is important as NLP researchers have increasingly recognised that, for many tasks, different points of view may be equally valid (Abercrombie et al., 2022; Aroyo and Welty, 2015; Basile et al., 2021a; Plank, 2022; Rottger et al., 2022), and that their aggregation can erase minority perspectives (Basile et al., 2021a; Blodgett, 2021).

One of the main challenges in implementing this new paradigm is the interpretation of disagreement. Disagreement between annotators may be due to two sources: 1) genuine differences in their subjective beliefs/perspectives, which can be desirable under this paradigm, or 2) task difficulty, ambiguity, or annotator error, all of which are undesirable. While agreement measures *between* annotators can give us an idea of task **subjectivity**, they provide little insight as to its **difficulty**, **ambiguity**, or the quality and attentiveness of the annotators themselves (Rottger et al., 2022).

In the following, we propose the use of *intra*-annotator agreement as a measure of subjectivity.

**The reliability-stability agreement matrix** What then, does it mean when individual annotators' interpretations are not stable, i.e., internally consistent? In addition to providing an

<sup>1</sup>Although there may be situations in which annotation consistency is not expected, such as longitudinal studies of attitudinal change.

additional layer of quality control, we suggest that measurement of label stability can help to interpret potential causes of *inter*-annotator disagreement. To this end, we propose the reliability-consistency matrix, a framework for mapping and interpreting the relationship between inter- and intra-annotator agreement in labelled datasets (Table 1).

		Stability (temporal within annotator)	
		High <i>intra</i>	Low <i>intra</i>
Reliability (between annotators)	High <i>inter</i>	Straight-forward / Good quality	Systematic errors/ Value changes
	Low <i>inter</i>	Variable perspectives (high subjectivity)	Ambiguous or difficult / Poor quality

Table 1: The reliability-stability matrix for *inter*- and *intra*- annotator agreement.

Under this framework, *inter*-annotator agreement and *intra*-annotator agreement, taken together, indicate the task’s ambiguity or complexity and its subjectivity level. *Inter*-annotator agreement measures reliability, while *intra*-annotator agreement measures stability. The resulting axes form a confusion matrix that describes four cases.

If both measures are high, we assume the task is unambiguous and relatively easy, and the annotator group relatively homogenous. Presumably, the quality of the guidelines and textual data is also good (Ide and Pustejovsky, 2017). In this scenario, the task or item should be relatively straightforward.

Where both agreement measures are low, we are likely to be faced with a highly ambiguous or difficult task or item—perhaps with multiple equally valid responses—or the annotation quality is poor.

If reliability is low, but consistency is high, the labels likely reflect the annotators’ varied but potentially equally valid subjective perspectives.

We do not foresee many situations where reliability is high yet consistency is low. Any agreement between inconsistent annotators would presumably be purely by chance or mass random spamming, i.e., systematic errors. Exceptions could include population-level value shifts over longer time intervals arising from awareness-raising events such as the #MeToo (Szekeres et al., 2020) and #BLM (Sawyer and Gampa, 2018) movements.

Our framework can be applied at the task- or dataset-level by computing the widely used chance-corrected agreement metrics, such as Cohen’s *kappa*, Krippendorff’s *alpha*, or Intra-class corre-

lation coefficient (ICC) for more than two raters (Landis and Koch, 1977), or to conduct qualitative analyses examining the reasons for label variation of individual instances.

We illustrate this framework in interpretation of the annotation experiments proposed in Section 3.

**Contributions** We suggest addition of intra-annotator consistency as a standard measure, and show how it complements existing reliability measures to distinguish reasons for label variation.

## 2 Intra-annotator agreement in the ACL Anthology

To get a snapshot of the extent to which intra-annotator agreement is reported in the NLP community, we conducted a systematic review of papers published in the *Anthology* of the Association for Computational Linguistics (ACL).<sup>2</sup> Here, we wish to discover for which tasks and what purposes NLP researchers collect and report on repeat annotations and evidence for how and when repeat items should be presented to annotators. Full details of the review methodology are available in Appendix A.

**To what extent and why is intra-annotator agreement reported in NLP?** When we conducted our study, the search and filtering process returned only 56 relevant publications out of more than 80,000 papers listed in the *Anthology*. In other words, a tiny fraction (around 0.07%) of computational linguistics and NLP publications in the repository report measurement of intra-annotator agreement.<sup>3</sup> Publication dates of included papers range from 2005 to 2022, with no trend towards increased reporting.

The only area of NLP in which intra-annotator agreement is somewhat regularly reported is machine translation (MT), which accounts for more than half of the included publications. Most of these were agreement measures on human evaluation of translation quality, with one on word alignment annotation for MT (Li et al., 2010). Several other publications on evaluating natural language generation also report measurement on human evaluation tasks (e.g. Belz and Kow, 2011; Belz et al., 2016, 2018; Jovanovic et al., 2005). Other included fields are semantics (e.g. Cao et al.,

<sup>2</sup><https://aclanthology.org/>

<sup>3</sup>We acknowledge that intra-annotator agreement is irrelevant to a large proportion of papers, but highlight that the number of publications which report it is nevertheless extremely low.

2022; Hengchen and Tahmasebi, 2021), syntax (e.g. Baldridge and Palmer, 2009; Lameris and Stymne, 2021), affective computing (including sentiment analysis (Kiritchenko and Mohammad, 2017) and emotion detection (Vaassen and Daelemans, 2011)), and automatic text grading (Cleuren et al., 2008; Downey et al., 2011). There is also one paper on abusive language detection (Cercas Curry et al., 2021).<sup>4</sup>

Where the authors motivate the collection of repeat annotations, they usually mention quality control or annotator consistency. Notably, no papers mention the possibility that intra-annotator inconsistency could be valid or informative beyond these factors, as we propose.

**Best practice for measuring intra-annotator agreement: how long should the label-relabel interval be?** When designing annotation tasks (such as ours in Section 3), it would be helpful to know when to present repeated items, thus avoiding annotators labelling from memory, which may not be an actual test of their consistency.

Over a quarter of the papers (15/56) do not provide enough information to determine the interval between initial and repeat annotations. In most other cases, either it can be inferred, or the authors explicitly state that re-annotations are conducted in the same session as the original annotation. Those that report more extended time before re-annotation leave intervals varying from a few minutes (Kiritchenko and Mohammad, 2017) to a year (Cleuren et al., 2008; Hamon, 2010).

Two papers do specifically investigate the effects of time on annotator consistency. Li et al. (2010) experimented with intervals of one week, two weeks, and one month, comparing intra-annotator agreement for these and finding that consistency on their word alignment annotation degraded steadily over time. (Kiritchenko and Mohammad, 2017) performed a similar study, comparing intra-annotator agreement on ratings (on a scale) that were conducted with intervals from a few minutes to a few days between the initial and repeat judgements. They too found that inconsistencies increased as a function of increase in interval.

### 3 Exploratory annotation experiments

We propose an exploratory annotation experiment to investigate the relationships between agreement

measures and the possible reasons for disagreements and inconsistencies. We wish to examine how strongly inter- and intra-annotator agreement levels correlate with the reasons for label variation on different tasks. We also investigate whether, as is commonly believed, specific task types are generally more subjective than others.

#### Hypotheses

At the individual annotation item level, for a given task and dataset:

- H1.1 *Subjective* annotation items have lower *inter*-annotator agreement than straightforward items, but higher *intra*-annotator agreement than *ambiguous* items.
- H1.2 *Ambiguous* annotation items have lower *inter*- and *intra*-annotator agreement than both straightforward and *ambiguous* items.

At the dataset/task level:

- H2 *Social* tasks—such as offensive language detection and sentiment analysis—are more *subjective* than *linguistic* tasks, like textual entailment or anaphora resolution. That is, stability is higher for social tasks than linguistic tasks.

**Data** We collect subsets of two English language datasets for social tasks that are commonly assumed to be subjective, and two linguistic tasks, thought of as objective (Basile et al., 2021b) (see Table 2).

These were selected because they (1) have limited label sets (of two or three classes), allowing for comparison across tasks; and (2) have been published with non-aggregated (i.e. annotator specific) labels, allowing us to include items with known inter-annotator disagreement in our subsamples.

**Methodology** We recruit crowdworkers from Prolific<sup>5</sup> to annotate a subset of from each of the tasks/datasets. Based on the evidence of our review (Li et al., 2010; Kiritchenko and Mohammad, 2017), we leave an interval of two weeks before we recall the annotators to collect a second round of annotations in order to measure their consistency.

We then recruit a second set of expert annotators<sup>6</sup> to annotate the examples that demonstrate internal and or external disagreement with rationalisations for these disagreements, using labels

<sup>4</sup>We provide a list of included papers in Appendix B.

<sup>5</sup><https://www.prolific.co/>

<sup>6</sup>PhD students in NLP recruited from our lab.

	Task	Dataset	Labels
<b>Social</b>	Offensive language detection	Leonardelli et al. (2021)	<i>Offensive/not offensive</i>
	Sentiment analysis	Kenyon-Dean et al. (2018)	<i>Positive/negative/objective</i>
<b>Linguistic</b>	Natural language inference/ textual entailment	Williams et al. (2018)	<i>Entailment/contradiction/ neutral</i>
	Anaphora resolution	Poesio et al. (2019)	<i>Referring/non-referring</i>

Table 2: Datasets used in the proposed annotation experiments.

based on Bhattacharya et al. (2019)’s Question Answer Differences dataset: *ambiguous*, *difficult* (e.g. requires world knowledge), *subjective*.

We also assess stability for this (meta-)task by measuring intra-annotator agreement on a subset of this data.

**Evaluation** We conduct a quantitative analysis of the correlation between items that exhibit low stability (*intra*-annotator disagreement) and the perceived reasons for the label differences. That is, we measure the Phi coefficient  $r_\phi$ <sup>7</sup> between the following two dichotomous variables:

A. Label stability:

- *stable*: those on which annotators are always *consistent*
- *unstable*: those on which annotators are *inconsistent*

B. Rationalisation of instability—items labelled as:

- *subjective*
- *ambiguous/difficult*

using the formula:

$$r_\phi = \frac{(bc - ad)}{\sqrt{(a + b)(c + d)(a + c)(b + d)}}$$

where  $a, b, c, d$  are the number of annotation items in the corresponding cells in Table 3.

	subjective	ambiguous
stable	a	b
unstable	c	d

Table 3: Contingency table for the two variables Task A annotator consistency and Task B instability rationalisation.

We will also conduct a qualitative analysis of the data to investigate the types of items on which annotators are inconsistent across the four tasks.

<sup>7</sup>Equivalent to Pearson’s  $r$  for two dichotomous nominal variables (Guilford, 1936).

## 4 Results

This version of the paper serves as a pre-registration placeholder (van Miltenburg et al., 2021): results will be published in the full version of this paper.

## 5 Conclusion

We have examined the role and use of intra-annotator agreement measures in NLP research. Calculation of such measures can act as an important quality control and could potentially provide insights into the reasons for disagreements between annotators. However, in a systematic review, we found that they are rarely reported in this field.

We have proposed a framework for the interpretation of inter- and intra-annotator agreement, the *reliability-stability agreement matrix*. We have also designed exploratory annotation experiments to investigate the relationships between these measures and perceptions of subjectivity and ambiguity in text items, which we will conduct in future research.

## 6 Ethical considerations

Because we recruit humans to work on data labelling, we will seek approval to undertake this study from our Institutional Review Board (IRB). Additionally, we will take the following measures:

**Compensation** We will pay the annotators at least the living wage in our jurisdiction (higher than the minimum wage, as recommended (as a minimum) by Shmueli et al. (2021)).

**Welfare** As some of the data to be labelled includes offensive language, we will:

- avoid recruiting members of vulnerable groups by restricting annotators to those aged over 18, and by providing annotators with comprehensive warnings prior to consenting to participate
- allow annotators to leave the study at any time

- keep the annotation task short to avoid lengthy exposure to material which may exceed ‘*minimal risk*’ (Shmueli et al., 2021).

**Privacy** All personal data of recruited annotators will be fully anonymised.

## A Systematic review methodology

For this review, we followed the established systematic review guidelines of the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement (Moher et al., 2009), as recommended by van Miltenburg et al. (2021):

1. Develop search query terms
2. Conduct search
3. Apply inclusion/exclusion criteria
4. Code included publications
5. Measure inter- and intra-annotator agreement (re-code subset of publications)
6. Synthesise results

The review covers all results retrieved from the Anthology’s search facility. The searches were conducted on September 14 2022. Following retrieval of the resulting publications, we applied the inclusion/exclusion criteria shown in Table 4.

<b>Include</b>	<b>Exclude</b>
Human annotation studies	No human annotation study is conducted (e.g. surveys/reviews of other work)
Repeated annotations are collected	Repeated annotations are not collected
Intra-annotator measurement is reported	Intra-annotator measurement not reported
Measurement conducted on manual labels applied by human annotators	Labelling is performed automatically
‘Intra-’ refers to repeat annotations of the same items by the same annotator	Term ‘intra-’ is used, but refers to agreement measurements between different items and/or annotators
Publication is a full paper	Posters, proceedings, proposals, technical system descriptions etc.

Table 4: Criteria for in/exclusion in/from the review.

The searches returned 138 publications. After removing duplicates, and applying the inclusion criteria we were left with 56 relevant publications in the Anthology.

## B Included papers

A list of included publications from the ACL Anthology that report intra-annotator agreement is presented in Table 5.

<b>Publication</b>	<b>NLP sub-field</b>	<b>Publication</b>	<b>NLP sub-field</b>
