Abstract

The automatic reading of text-intensive images represents a significant advancement toward achieving Artificial General Intelligence (AGI). In this paper we present KOSMOS-2.5, a multimodal literate model for machine reading of textintensive images. Pre-trained on a large-scale corpus of textintensive images, KOSMOS-2.5 excels in two distinct yet complementary transcription tasks: (1) generating spatially-aware text blocks, where each block of text is assigned spatial coordinates within the image, and (2) producing structured text output that captures both style and structure in markdown format. This unified multimodal literate capability is achieved through a shared decoder-only autoregressive Transformer architecture and task-specific prompts. Building on this foundation, we fine-tune KOSMOS-2.5 for document understanding tasks, resulting in a document understanding generalist named KOSMOS-2.5-CHAT. Additionally, a large corpus of 357.4 million document pages spanning diverse domains was curated for pre-training. We evaluate KOSMOS-2.5 on two newly proposed benchmarks, OCREval and MarkdownEval, for document-level text recognition and image-to-markdown generation, demonstrating impressive literate capabilities comparable to GPT-40. KOSMOS-2.5-CHAT achieves performance comparable to other state-of-the-art generalists that are five times larger (1.3B vs. 7B) across nine text-rich visual question answering benchmarks. Models and code have been available at https://aka.ms/kosmos25.

1 Introduction

Multimodal large language models (MLLMs) extend the capabilities of large language models (LLMs) to multimodal tasks, enabling them to process and generate responses from both textual and visual inputs (Zhang et al. 2023b; Liu et al. 2024b; ChatGPT 2022; Touvron et al. 2023). However, while existing MLLMs have primarily focused on natural images, the challenge of effectively reading and understanding text-intensive images—such as academic papers, receipts, design documents, and web pages—remains underexplored.

Traditional Optical Character Recognition (OCR) methods are primarily designed for generating line-level text content and capturing its spatial positions within an image. Although these methods preserve layout information, they often neglect the document-level reading order and structural integrity that are crucial for accurate document understanding. On the other hand, markdown-formatted text offers significant advantages over plain text by explicitly distinguishing between different structural elements—such as tables, lists, and headings—through specific tokens. Current approaches are either limited to line-level text recognition (Ye et al. 2023a; Hu et al. 2024; Li et al. 2023c) or focus on structured parsing within a specific document category (Blecher et al. 2023), making it difficult to achieve comprehensive document-level reading and understanding capabilities across diverse categories.

Motivated by these observations, we present KOSMOS-2.5, a multimodal literate model designed to address the unique challenges of reading and understanding textintensive documents, including capturing the reading order and structural integrity of the content. As illustrated in Figure 1, KOSMOS-2.5 is pre-trained on two distinct yet complementary generative tasks: document-level text recognition and image-to-markdown generation. The first task involves generating spatially-aware text blocks, assigning text lines to their corresponding spatial coordinates within the original text-rich image. The second task focuses on producing structured text output that captures both style and structure in markdown format. Both tasks are performed within a unified framework using task-specific prompts, leveraging a shared Transformer architecture that combines a ViT-based vision encoder and a Transformer-based language decoder connected by a resampler module (Dosovitskiy et al. 2021; Lee et al. 2023; Alayrac et al. 2022).

To realize the potential of our pre-trained model and validate its effectiveness in downstream understanding tasks, we further fine-tune KOSMOS-2.5 for document understanding tasks, resulting in **KOSMOS-2.5-CHAT**, which can answer user-provided questions about text-rich images. Despite having only 1.3B parameters, KOSMOS-2.5-CHAT achieves performance comparable to other state-of-the-art generalists with over 7B parameters on various text-rich visual question answering benchmarks.

Given the absence of a comprehensive document reading dataset, we curated a large corpus of **357.4 million document pages**, including scanned documents, general documents, academic papers, web pages, design images, handwritten texts, mathematical content, and project documents. Each document is annotated with text lines with bounding boxes or markdown formats. This dataset was constructed using an

^{*} Equal contribution. † Corresponding author.

Figure 1: KOSMOS-2.5 is a multimodal document foundation model that takes text images as input and generates spatially-aware texts (i.e., texts with bounding boxes) or markdown-formatted texts (i.e., texts with markdown elements), following different task prompts, respectively. The model possesses the ability to comprehensively perceive textual content, its spatial context, and nuances of formatting and style within a unified framework. KOSMOS-2.5-CHAT is fine-tuned from KOSMOS-2.5. It is a visual document understanding generalist that can answer user-provided questions about text-rich images from various domains.

automatic pipeline for data collection, filtering, and quality control, offering valuable insights for future research.

Existing document reading benchmarks primarily focus on line-level text reading capabilities (Liu et al. 2023b) or are limited to specific domains, such as converting academic papers to markdown format (Blecher et al. 2023). To comprehensively evaluate models' capabilities in document-level text recognition and image-to-markdown generation tasks, we introduce two extensive benchmarks: **OCREval** and **MarkdownEval**. Specifically, OCREval contains 2,297 samples, while MarkdownEval includes 5,633 samples. The benchmarks cover a diverse range of document categories, including handwritten texts, design documents, receipts, academic papers, web pages, mathematical content, tables, and more. Experimental results on these benchmarks demonstrate that KOSMOS-2.5 exhibits impressive literate capabilities on par with GPT-40 (GPT-4 2023).

The contributions of this work are summarized as follows:

- We propose two distinct yet cooperative document reading tasks for pre-training a foundational document model capable of machine reading and understanding the order and structure of text-intensive documents. The pre-trained KOSMOS-2.5 demonstrates impressive multimodal literate capabilities on par with GPT-40, and the fine-tuned KOSMOS-2.5-CHAT achieves competitive results across nine document understanding benchmarks.
- We curated a large and diverse corpus consisting of 357.4 million text-rich document images, with text lines annotated with bounding boxes or in markdown format. The automated data curation pipeline provides valuable insights for future research.

 We introduce two comprehensive benchmarks, OCREval and MarkdownEval, to provide thorough evaluations of document-level machine reading capabilities.

2 KOSMOS-2.5

2.1 Model Architecture

The architecture of KOSMOS-2.5 comprises a vision encoder and a language decoder, connected through a resampling module to reduce the sequence length of the image (Alayrac et al. 2022), as illustrated in Figure 2. The **vision encoder** is initialized from the Pix2Struct-Large model's encoder (Lee et al. 2023), which is based on the Vision Transformer (ViT) (Dosovitskiy et al. 2021). Consistent with Pix2Struct (Lee et al. 2023), we employ a variable resolution strategy and extract the maximum number of fixed-size patches that can fit within a predefined sequence length.

The **resampler** compresses the image sequence into a shorter, fixed number of tokens:

$$H_0 = f(I) \tag{1}$$

$$H_1 = \text{Attention}(V, [V; H_0], [V; H_0])$$
 (2)

where I is the input image, f is the encoder function, V represents a set of predefined soft tokens, and [;] denotes the concatenation operator. The **language decoder** is based on a Transformer architecture and is designed to condition on both image and text contexts for next-token prediction. Details on the hyperparameters can be found in Appendix A.1.

Figure 2: The model architecture of KOSMOS-2.5 leverages a shared Transformer architecture that combines a ViT-based vision encoder and a Transformer-based language decoder connected by a resampler module.

Training Stage	Task	Definition	Prompt
Dro training	Document-level Text Recognition	Generating spatially-aware text blocks, where each block of text is assigned its spatial coordinates within the image	<s><image/>Image Embedding<ocr>$igcup_{n=1}^N \left(\mathbf{B}_n \oplus \mathbf{T}_n ight)$</ocr></s>
r re-training	Image-to-Markdown	Producing structured text output that captures	<s><image/>Image Embedding<md></md></s>
	Generation	styles and structures into the markdown format	[Markdown lext]
Fine-tuning	Document Understanding	Answering the user-provided text-related questions about text-intensive images	<s><image/>Image Embedding<md> A chat between a curious user and an artificial intelligence assistant. The assistant gives helpful, detailed, and polite answers to the user's questions. USER: [Question] ASSISTANT: [Answer]</md></s>

Table 1: Tasks, prompts, and response sequence formats used to train KOSMOS-2.5. Special tokens $\langle s \rangle$ and $\langle /s \rangle$ denote sequence boundaries, while $\langle image \rangle$ and $\langle /image \rangle$ indicate the start and end of image embeddings. For document-level text recognition tasks, the operator \oplus represents the concatenation of the text line T_n and its bounding box B_n . During pre-training, special tokens $\langle ocr \rangle$ and $\langle md \rangle$ denote document-level text recognition and text-to-markdown generation tasks, respectively. For visual document understanding tasks, we use the same format as text-to-markdown generation tasks since these do not require bounding box outputs.

2.2 Image and Text Representation

The image representation is derived from the image encoder and resampler as described in Section 2.1. Text representation is obtained through text tokenization and embedding. For markdown text, we directly tokenize it while preserving all special characters and formatting indicators. For text lines with bounding boxes, we convert the coordinates into discrete location tokens, similar to KOSMOS-2 (Peng et al. 2023).

We introduce a set of 2L + 2 specialized tokens: $\langle x_0 \rangle$, $\langle x_1 \rangle$, ..., $\langle x_{L-1} \rangle$, $\langle y_0 \rangle$, ..., $\langle y_{L-1} \rangle$, $\langle bbox \rangle$, and $\langle bbox \rangle$, which correspond to the coordinates and the start and end markers of a bounding box. The coordinates are obtained by rounding down the actual positions after resizing the images.

Consider a document T with N text lines. Each line is represented as $\mathbf{T}_n = \{w_1^{(n)}, w_2^{(n)}, \ldots, w_{M_n}^{(n)}\}$, where M_n is the number of words in the *n*-th text line. The bounding box for \mathbf{T}_n is then expressed as $\mathbf{B}_n =$

blox>< $x_{tl}^{(n)}$ >< $y_{tl}^{(n)}$ >< $x_{br}^{(n)}$ ></blox>, where the coordinates represent the top-left and bottom-right corners of the bounding box.

2.3 Pre-training on Document Reading

Pre-training Tasks. Traditional Optical Character Recognition (OCR) tasks primarily focus on generating line-level text content and capturing its spatial positions within an image. While OCR preserves the layout positions of document text, it often overlooks the document-level reading order and structural integrity, both crucial for comprehensive document understanding. In contrast, markdown-formatted text provides an advantage over plain text by explicitly distinguishing various structural elements, such as tables and lists, using specific tokens.

To effectively learn the layout and structure of documents, we propose two complementary generative tasks for pretraining a document foundation model: document-level text

Format and Task	Document Category	Description	Page Num	Sampling Ratio

recognition and image-to-markdown generation, as detailed in Table 1.

Training Objective and Formats. We train the model to predict outputs based on the input image context and task-specific prompts. The training objective is to minimize the cross-entropy loss for next-token prediction, commonly known as autoregressive language modeling (Radford et al. 2018). Table 1 illustrates the formats for model training prompts and response sequences.

The prompt is constructed by concatenating the image representation with a task-specific special token. The response corresponds to the text output of the tasks: text lines with bounding boxes for document-level text recognition and markdown text for the image-to-markdown generation task. A qualitative example is provided in Appendix A.4 to illustrate the model's input and output. **Pre-training Data.** Our training data is collected using an automated pipeline from diverse sources, resulting in a large corpus of 357.4 million document images, annotated with text lines using bounding boxes or in markdown format. As shown in Table 2, our pre-training dataset encompasses a wide range of document types, including scanned documents, academic papers, web pages, design images, mathematical content, handwritten text, and more. Compared with the training data used by existing models in Table 3, KOSMOS-2.5 leverages the largest and most diverse corpus, which significantly enhances the model's adaptability and generalization across different domains.

We apply **filtering and quality control during data curation**. We use fastText for language identification (with a threshold of 0.5) to filter out non-English documents from the entire pre-training dataset. To ensure content diversity within each source, we use MinHash (Broder 1997) to identify and remove redundant pages, applying the same parameters as (Lee et al. 2021), with document pairs having a similarity score of 0.8 or higher marked as duplicates.

For image-to-markdown data sourced from README, DOCX, LATEX, and HTML files, we encountered discrepancies between the content in text images and their corresponding markdown sequences due to conversion issues. To refine the data, we evaluate token overlap between images and markdown files, requiring a token intersection-to-union ratio greater than 0.95 for inclusion. Details of the processing procedures for each document category are provided in Appendix A.5, along with sample training data in Appendix A.8, aiming to offer transparent and reproducible guidelines for future research and applications.

2.4 Fine-tuning on Document Understanding

We fine-tune KOSMOS-2.5 on document understanding datasets, referring to the fine-tuned model as KOSMOS-2.5-CHAT. KOSMOS-2.5-CHAT is designed to answer diverse user-provided questions about text-intensive images from various domains. To better retain the reading capability of KOSMOS-2.5, we freeze the visual encoder of the pre-trained model and fine-tune the resampler and language model using a document understanding task prompt (Line 3 in Table 1), where [Question] and [Answer] represent a question-answer pair from the dataset.

3 Experiments

3.1 Model and Training Configurations

Following Pix2Struct (Lee et al. 2023), we employ a short warmup phase of 20k steps to facilitate faster convergence during the pre-training stage. In this phase, the model learns to read text snippets from synthetic images rendered with random colors and fonts. Due to the substantially larger volume of layout-based data compared to markup-based data, we initially trained the model for 100k steps using only the layout-based dataset. We then combined the two datasets for an additional 140k steps of training. The total training involved approximately 260 billion tokens.

Our text tokenization is based on the cl100k_base tiktoken tokenizer¹, with 8,194 specialized tokens introduced for coordinates and bounding box markers. The newly added word embeddings for location tokens are randomly initialized, with all parameters updated during training. We also incorporate data augmentation techniques from TrOCR (Li et al. 2022b) to enhance the model's robustness.

KOSMOS-2.5 contains a total of 1.3 billion parameters. Further details on model architecture and training hyperparameters are provided in Appendix A.1.

Tota	5,693	

Table 5: Summary of document categories, data sources, and the number of samples in the MarkdownEval benchmark.

3.2 Evaluation on Document Reading

Benchmarks. To comprehensively evaluate models' capabilities in document-level text recognition and image-to-markdown generation tasks, we collected the OCREval and MarkdownEval benchmarks. The **OCREval benchmark** consists of 2,297 images from the test sets of 13 datasets, covering categories such as mathematical content, handwritten images, design images, receipts, digitally born documents, and web pages. The **MarkdownEval benchmark** includes 5,693 images spanning categories such as mathematical equations, academic papers, tables, general documents, and project documentation. The respective categories, data sources, and sample counts are detailed in Table 4 and Table 5. More data processing details are provided in Appendix A.6.

Metrics. The **metrics for OCREval** include word-level *F1*, *IOU*, and *NED* to evaluate document-level OCR performance. The **metrics for MarkdownEval** include Normalized Edit Distance (NED) and Normalized Tree Edit Distance (NTED) for assessing image-to-markdown generation. NED is a string-based comparison metric, while NTED measures tree edit distance normalized by the number of nodes, capturing structural differences in parse trees. This dual evaluation framework considers both lexical accuracy and the preservation of the original hierarchical structure inherent in the Markdown format. Further details on the evaluation metrics are provided in Appendix A.2 and Appendix A.3.

Results. KOSMOS-2.5 is a unified framework that facilitates multitasking with tasks determined by the provided prompts. We compared KOSMOS-2.5 against state-of-theart document reading models on OCREval (Table 6) and MarkdownEval (Table 7). For the document-level text recognition task, KOSMOS-2.5 outperforms existing models in reading text-intensive images. For instance, KOSMOS-2.5 surpasses Vary_{Base} by a significant margin despite having a smaller model size (1.3B vs. 7B parameters). KOSMOS-2.5 also achieved the best performance across all image types on MarkdownEval. Notably, GPT-4o's omission of markdown symbols affected its NTED scores slightly. For example, while e² should be represented as e² in markdown, GPT-40 outputs e^2 directly. For models adhering to markdown standards (e.g., Vary and Nougat), KOSMOS-2.5 consistently outperforms them, benefiting from better

layout understanding in text recognition.

3.3 Evaluation on Document Understanding

Settings. Fine-tuned on downstream datasets, KOSMOS-2.5-CHAT is capable of addressing a wide range of document understanding tasks. We fine-tuned KOSMOS-2.5-CHAT on the standard training sets of ten diverse document understanding datasets. These datasets cover general documents (DocVQA (Mathew, Karatzas, and Jawahar 2020), InfoVQA (Mathew et al. 2022), DeepForm (Svetlichnaya 2020), KLC (Stanislawek et al. 2021)), tables (WTO (Pasupat and Liang 2015), TabFact (Chen et al. 2020)), charts (ChartVQA (Masry et al. 2022)), natural images (TextVQA (Singh et al. 2019), TextCaps (Sidorov et al. 2020)), and webpage screenshots (VisualMRC (Tanaka, Nishida, and Yoshida 2021)). Evaluation is performed on the official test sets of nine public document understanding benchmarks. We did not evaluate on TextCaps due to the unavailability of the official evaluation server at this time.

Results. Table 8 presents the experimental results compared to state-of-the-art OCR-free models. Among models with fewer than 2B parameters, KOSMOS-2.5-CHAT outperforms PixStruct_{LARGE} and Donut across various benchmarks without task-specific fine-tuning. Compared to models exceeding 7B parameters, KOSMOS-2.5-CHAT delivers competitive performance on benchmarks covering documents, tables, and charts, including DocVQA, InfoVQA, DeepForm, KLC, WTQ, and ChartVQA. These results highlight the effectiveness of KOSMOS-2.5-CHAT in handling complex document understanding tasks.

4 Related Work

4.1 Multimodal Large Language Models

Multimodal large language models (MLLMs) can be broadly categorized into LLM-centric scheduling systems and end-to-

end trainable multimodal systems. LLM-centric scheduling systems leverage various vision foundation models, orchestrating them in a language-centric manner (Wu et al. 2023; Yang et al. 2023; Liang et al. 2023; Shen et al. 2023; Chen et al. 2023c; Surís, Menon, and Vondrick 2023; Chen et al. 2023b). On the other hand, end-to-end trainable multimodal systems integrate vision and language models into a unified framework (Hao et al. 2022; Alayrac et al. 2022; Huang et al. 2023a; Peng et al. 2023; Huang et al. 2021; Xue et al. 2021; Zhu et al. 2023; Huang et al. 2023b; Li et al. 2023; Dai et al. 2023; Liu et al. 2023; Liu et al. 2023; Chen et al. 2023; Su et al. 2023; Zhang et al. 2023a; Gao et al. 2023; Koh, Salakhutdinov, and Fried 2023; Li et al. 2023; Hong et al. 2023; Kondratyuk et al. 2023; Bai et al. 2023; Hong et al. 2024; Yao et al. 2024; Wei et al. 2024).

Our model falls into the latter category, sharing similarities with grounded multimodal models like KOSMOS-2 (Peng et al. 2023), Shikra (Chen et al. 2023a), and ChatSpot (Zhao et al. 2023), which output object locations in natural images. However, KOSMOS-2.5 uniquely focuses on text-image reading and understanding capabilities, tackling the challenge of producing high-quality document layouts while maintaining the structural integrity crucial for document understanding.

4.2 Document Reading and Understanding

Document reading and understanding leverage AI to automatically read, comprehend, and extract information from documents (Cui et al. 2021; Xu et al. 2020, 2021b,a; Huang et al. 2022; Kim et al. 2021; Chen et al. 2022; Li et al. 2021b, 2022a, 2021c; Appalaraju et al. 2021; Wang, Jin, and Ding 2022; Gu et al. 2022; Li et al. 2021a; Chen et al. 2024; Yu et al. 2023; Li et al. 2023c; Liu et al. 2024c). Representative document foundation models like LayoutLMv3 integrate text, layout, and image information during pre-training, excelling in tasks like key information extraction and document question answering (Huang et al. 2022). Donut (Kim

Table 8: Experimental results on document understanding benchmarks. The models listed above the line have more than 7B parameters, while those below the line are smaller models. The superscript '*' indicates models fine-tuned separately on each downstream task. Among models with fewer than 7B parameters, the best results are marked in **bold**.

et al. 2021) introduces an OCR-free document understanding Transformer, directly mapping input document images to desired outputs. Models like Pix2Struct (Lee et al. 2023), HRVDA (Liu et al. 2024a), and the mPLUG-DocOwl series (Ye et al. 2023a; Hu et al. 2024) pre-train vision encoders on document reading tasks, resulting in impressive document understanding performance. KOSMOS-2.5 scales up document pre-training to include up to 357.4 million document pages and more challenging tasks, significantly enhancing the model's reading and understanding capabilities.

Nougat (Blecher et al. 2023) similarly parses documents into markup language, but its focus is limited to scientific documents. In contrast, KOSMOS-2.5 excels across a broader range of documents and generalizes well to document understanding tasks. Recent works like DocPedia (Feng et al. 2023) enhance MLLMs' text-rich image understanding by processing visual input in the frequency domain for high-resolution capabilities. Approaches like TextSquare (Tang et al. 2024a), TRINS (Zhang et al. 2024), and LLaVAR (Zhang et al. 2023b) enhance reading abilities by using publicly available OCR tools and closed-source MLLMs to generate instructiontuning data for text-rich images. LLaVA-read further uses open-source OCR tools to extract text and layout information for language models. UReader (Ye et al. 2023b) introduces a shape-adaptive cropping module to efficiently encode lowresolution sub-images. Meanwhile, Monkey (Li et al. 2023c) boosts training efficiency and resolution, excelling in image captioning and text-rich document processing. However, these methods rely on pre-trained vision encoders without document-specific pre-training, which limits their performance. After extensive pre-training, KOSMOS-2.5 achieves strong document understanding performance by fine-tuning on publicly available benchmarks only, without needing complex module designs, OCR tools, or closed-source MLLMs.

4.3 Document Reading Benchmarks

Existing OCR evaluation benchmarks like OCRBench (Liu et al. 2023b) or DocLocal4K (Hu et al. 2024) mainly focus on text-line recognition tasks. Textmonkey (Liu et al. 2024c) evaluates the model on natural images only. In contrast, our proposed OCREval is the first benchmark specifically designed to assess document-level text recognition, which demands more advanced recognition capabilities. For markdown evaluation, Nougat (Blecher et al. 2023) restricts its performance assessment to academic papers from ArXiv. In contrast, our MarkdownEval offers a more comprehensive assessment by covering a wider range of image domains, providing a more robust assessment of model capabilities.

5 Conclusion and Future Work

In summary, this work advances document-level machine reading by introducing a novel pre-training framework and demonstrating its effectiveness through impressive performance on diverse benchmarks. Our pre-trained model, KOSMOS-2.5, excels in document reading, while our finetuned model, KOSMOS-2.5-CHAT, achieves competitive results in document understanding benchmarks. The extensive corpus of 357.4 million annotated document images and the development of OCREval and MarkdownEval benchmarks provide comprehensive tools for evaluating and furthering research in document intelligence. Despite these promising results, our current model faces some limitations, offering valuable future research directions. For instance, documents spanning multiple pages pose a challenge as they typically demand holistic processing and comprehension. Meanwhile, it is also feasible that KOSMOS-2.5 allows for multiple image pages interleaved with text as input; however, managing long context remains a vital issue we aim to address in future work. In the broader research landscape, a significant direction lies in advancing model scaling capabilities. With an expanding range of tasks and complexities, scaling the model to handle larger data volumes is crucial for multimodal literate models.

A Appendix

A.1 Model and Training Hyperparameters

Model and training hyperparameters are demonstrated in Table 9 and Table 10.

Modules	Hyperparameters	
	Patch size	16
	Patch embed hidden size	768
	Number of layers	18
Imaga Encodor	Hidden size	1,536
Image Encoder	FFN inner hidden size	3,968
	Attention heads	24
	Activation function	GeLU
	Max sequence length	4,096
	Number of layers	1
Resampler	Hidden size	1,536
	Output sequence length	2,048
	Number of layers	24
	Hidden size	1,536
	FFN inner hidden size	6,144
	Attention heads	16
Language Decoder	Activation function	GeLU
	Vocabulary size	108,481
	Max sequence length	4,096

Table 9: Model Hyperparameters of KOSMOS-2.5

Hyperparameters	Pre-training	Fine-tuning
Training steps	260,000	3000
Warmup steps	375	100
Batch size	1,0	24
Optimizer	Ada	mW
Learning rate	2e	-4
Learning rate decay	Lin	ear
Adam β	(0.9,	0.98)
Weight decay	0.0)1
Dropout	0.	1

Table 10: Training hyperparameters of KOSMOS-2.5

A.2 OCR Evaluation Metrics

F1. The F1 score is a commonly used evaluation metric for measuring the accuracy of models in classification tasks. It is the harmonic mean of Precision and Recall, offering a balanced measure that considers both false positives and false negatives. In the OCR task, the F1 score will be used to assess the effectiveness of OCR models in recognizing words from images. Precision is the ratio of correctly recognized words to the total number of words detected by the model. Recall is the ratio of correctly recognized words to the total number of actual words. The F1 score is the harmonic mean of Precision and Recall, and it is calculated as follows:

$$Precision = \frac{TP}{TP + FP}$$

$$Recall = \frac{TP}{TP + FN}$$
$$F1 = 2 \cdot \frac{Precision \cdot Recall}{Precision + Recall}$$

where TP is the number of correctly recognized words, FP is the number of incorrectly recognized words, and FN is the number of missed words.

IoU. Intersection over Union (IoU) is a critical evaluation metric for assessing the performance of object detection models, including OCR textline detection. IoU measures the overlap between the predicted bounding box and the ground truth bounding box, providing a quantitative measure of how well the model has detected the textlines in an image. The formula for IoU is as follows:

$$IoU = \frac{Area of Intersection}{Area of Union}$$

NED. Normalized Edit Distance (NED) is an extension of the Edit Distance (Levenshtein Distance) metric, commonly used to assess the similarity between two text strings. The calculation of NED can be found in Appendix A.3.

A.3 Image-to-markdown Generation Evaluation Metrics

In light of the unique nature of the image-to-markdown conversion task, assessing the quality of the generated markdown necessitates specialized metrics. We adopt a two-fold evaluation scheme: Normalized Edit Distance (NED) and Normalized Tree Edit Distance (NTED), considering both the lexical accuracy and the preservation of the original structural elements. The NED is formulated as

$$NED = 1 - \frac{1}{N} \sum_{i=1}^{N} D(s_i, \hat{s}_i) / \max(\text{len}(s_i), \text{len}(\hat{s}_i))$$

where N, s, and \hat{s} denote the number of samples, prediction, and ground truth, respectively. $D(\cdot, \cdot)$ and $len(\cdot)$ represent the edit distance function and the length of a string. The *NED* value ranges from 0 to 1, with a higher *NED* value indicating the prediction is closer to the ground truth.

However, given the hierarchical structure inherent to markdown, relying solely on a string-based comparison metric like NED can be insufficient. Thus, we adopt NTED as an additional evaluation metric for structural differences. NTED is a tree edit distance normalized by the number of nodes in the tree, considering the structural discrepancies between parse trees. Specifically, the predicted markdown sequence is first transformed into an HTML tree. Then, the tree edit distance between the prediction and the ground truth is calculated using the ZSS algorithm (Zhang and Shasha 1989). The NTED is formulated as

$$NTED = 1 - \frac{1}{N} \sum_{i=1}^{N} \text{TD}\left(t_i, \hat{t}_i\right) / \max\left(\text{node}(t_i), \text{node}(\hat{t}_i)\right)$$

where N, t, and \hat{t} signify the number of samples, the HTML tree of prediction, and the HTML tree of ground truth, respectively. Besides, $TD(\cdot, \cdot)$ and $node(\cdot)$ stand for the tree edit distance function and the number of nodes in a tree.

Figure 3: KOSMOS-2.5's outputs given the same text image and different task prompts.

A.4 Qualitative Example

We illustrate an example in Figure 3, showcasing the model outputs produced by KOSMOS-2.5 with various task prompts when presented with the same input text image. For document-level text recognition task, KOSMOS-2.5 produces the following text sequence, which includes textual content and corresponding bounding boxes:

For image-to-markdown generation task, KOSMOS-2.5 generates the text sequence in Markdown format:

text positions and recognizes text content. Moreover, it adeptly captures the styles and structures present within the text image, including elements like titles, bullet points, tables, and bold text. Section A.7 provides the full output sequence using different task prompts for this example. Furthermore, KOSMOS-2.5 is compatible with more powerful LLMs like GPT-3.5 or GPT-4. The output from our model can serve as contexts for LLMs, enhancing their capabilities through further prompt engineering.

A.5 Pre-training Data Processing

The pre-training data has a wide coverage, and each type of data requires a different processing workflow, which is introduced as follows:

Scanned Document We use the Microsoft Read API ³ to extract text and layout information.

General Document, Academic Paper, Design We first compile and convert arXiv papers, SEC files, and PowerPoint slides into PDF files. Together with other general PDFs and poster, we employed the PyMuPDF parser ⁴ to extract text and layout information efficiently.

Web Page We also include webpage screenshots in the model pre-training to diversify the layout distribution further. We collect the webpage URLs from the English portion of the mC4 dataset. Playwright ⁵ is used to access a specified URL and open the webpage. The HTML content of the page is extracted and parsed using the lxml library ⁶ to obtain a Document Object Model (DOM) tree representation. This

³https://learn.microsoft.com/en-us/azure/ai-services/computervision/overview-ocr#read-api

⁴https://github.com/pymupdf/PyMuPDF

⁵https://github.com/microsoft/playwright-python ⁶https://lxml.de/

DOM tree is traversed, examining the XPath of each element within it. This traversal aims to determine whether each element is visible and retrieve information about its bounding boxes.

Mathematical In CROHME, each piece of data is an individual formula. We randomly select between 5 to 15 formulas and paste them onto a single blank page at random positions for formula recognition in page level.

Handwritten We downloaded 5,427 handwritten fonts from Google Fonts, and for each textline generation, we randomly select one of these fonts.

General Document (markdown) The Microsoft Office WORD files have been extensively used in existing research like TableBank (Li et al. 2020) and ReadingBank (Wang et al. 2021). We collect WORD DOCX files and convert them into texts with markdown. First, we use Pandoc to convert the XML content within the DOCX files into markdown files. As Pandoc keeps the "¡table¿" tags to represent the tabular cells in the generated markdown, we further identify all the tables and use markdownify ⁷ to convert them into the markdown formats. Finally, the original DOCX files are converted into PDF files, and each page is aligned to the corresponding span of the markdown content based on a heuristic method.

Academic Paper (markdown) LaTeX documents from arXiv have been used to generate PDF files to obtain texts with bounding boxes. Meanwhile, we also convert the LaTeX content into the markdown texts. Similar to Nougat (Blecher et al. 2023), LaTeXML⁸ is used to convert the LaTeX code into the HTML sequence, which is further transformed into the markdown format. Different from Nougat, we keep all the tables at the beginning of the page as most LaTeX users prefer to position tables with "[t]" or "[h]" instead of "[b]". Meanwhile, we also convert the table content from the LaTeX format into the markdown format.

Project Document (markdown) In addition to layoutbased data, we collect markup-based data for the pre-training. We collect "README.md" files from many GitHub projects and convert these files into HTML using Pandoc⁹. Then, wkhtmltopdf¹⁰ is used to obtain the images from the generated HTML content.

Web Page (markdown) The most straightforward way to obtain markdown resources from HTML webpages is through web scraping. However, webpages are often cluttered with various layouts and styles, resulting from the misuse of HTML tags. Moreover, HTML pages may include extraneous elements, such as advertisements, navigation menus, or formatting elements, making extracting clean and meaningful content challenging. To overcome these obstacles, we employ Playwright, a fast and reliable end-to-end testing framework for the web. The library allows us to navigate the HTML structure, filter out non-essential elements, and extract the relevant text content. We also apply custom rules and regular expressions to further refine the extracted text and format it as markdown, ensuring that the resulting markdown files are coherent and readable.

A.6 Evaluation Data Processing

OCREval. We constructed the OCREval comprising 2,297 samples, covering data from various domains. The details of each dataset's construction are provided below:

- **Design.** We used the Microsoft Read API to obtain OCR results for MARIO-LAION, MARIO-OpenLibrary, and MARIO-TMDB, followed by manual verification to ensure the accuracy of the ground truth. For MJ&ST, MJSynth consists of single-line textlines, which we randomly selected and placed multiple textlines on a single page to create page-level OCR test samples. For Synth-Text, we used the provided text and bounding box as the OCR ground truth.
- **Receipt.** For SROIE and CORD, we use their official annotations, which are carefully annotated by crowd workers and not from third-party OCR results. For Receipts crawled from the internet, we used Bing's image search engine¹¹ with the keyword "receipt" to find relevant images. Subsequently, we used the Microsoft Read API to obtain OCR results and manually verified them, filtering out non-English receipts.
- **Others.** The processing steps for Handwritten, Academic paper, General, and Web Page are consistent with those used in the pre-training phase, as detailed in Appendix A.5.

To ensure the accuracy of the OCR ground truth, we utilized the provided OCR ground truth for publicly available datasets. For datasets without provided ground truth and for our own constructed dataset, we obtained OCR results using Microsoft's Read OCR engine¹² and then manually check them to ensure accuracy.

MarkdownEval. We constructed a dataset called markdownEval, consisting of 5,633 test samples, to evaluate the model's understanding of image across various domains. The details of each dataset's construction are provided below:

- **Math Image.** Both CROHME Math and Ima2LaTeX-100k consist of formulas and their corresponding LaTeX source code. We used Pandoc¹³ to convert the LaTeX source code into Markdown format and then randomly selected multiple samples to place on a single page to create test samples.
- **Table.** We extracted the LaTeX source code for tables from arXiv sources and then compiled it using pdfLa-TeX¹⁴ to obtain table images. Subsequently, we used Pandoc to convert the LaTeX source code into Markdown format to create test samples.
