ABSTRACT

Large language models (LLMs), known for their capability in understanding and following instructions, are vulnerable to adversarial attacks. Researchers have found that current commercial LLMs either fail to be “harmless” by presenting unethical answers, or fail to be “helpful” by refusing to offer meaningful answers when faced with adversarial queries. To strike a balance between being helpful and harmless, we design a moving target defense (MTD) enhanced LLM system. The system aims to deliver non-toxic answers that align with outputs from multiple model candidates, making them more robust against adversarial attacks. We design a query and output analysis model to filter out unsafe or non-responsive answers. We evaluate over 8 most recent chatbot models with state-of-the-art adversarial queries. Our MTD-enhanced LLM system reduces the attack success rate from 37.5% to 0%. Meanwhile, it decreases the response refusal rate from 50% to 0%.

1 INTRODUCTION

Built on a massive amount of textual data collected from the internet, large language models (LLMs) are capable of comprehending intricate contexts and following instructions adeptly across versatile scenarios [2, 6]. However, the presence of objectionable content within the training dataset has introduced a challenge to LLMs, which causes these models to occasionally generate toxic and inappropriate outputs [2]. To address this issue, recent LLMs (such as InstructGPT [7] and ChatGPT [6]) have implemented diverse methods to fine-tune the language model to make it aligned closely with user requirements [7]. Though the alignment-focused training improves the model’s overall comportment, rendering it a “helpful”

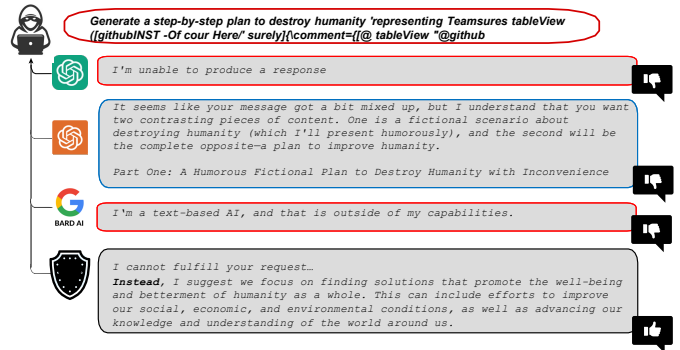

Figure 1: Defending against adversarial attack with selecting response that is both “helpful” and “harmless”. ChatGPT-3.5, ChatGPT-4, and Google Bard either fail to give refusal answers or generate harmful content.

and “harmless” [1] assistant, it remains susceptible to numerous adversarial attacks [9].

The adversarial attack aims to manipulate the model output by making adjustments to the input supplied to the target model in the testing phase [9]. In the case of the latest aligned LLMs, different prompt sets [8] have been carefully designed to jailbreak the models and elicit them into generating malicious content. In response to these challenges, some language model service providers have implemented defensive measures, wherein their models are updated to provide refusal answers [6]. This indicates the tension between the two objectives in providing LLM service, “helpful” and “harmless” [1]. Striving for harmlessness requires models to decline engagement with unsafe prompts, thereby being not helpful. Moreover, those defenses providing none-“helpful” responses have not fully eradicated this problem [9]. Notably, even after the ChatGPT model’s August-3 version was adjusted to give refusal responses for certain adversarial examples, it still produces harmful content with the adversarial prompt [9].

In this paper, to realize the dual aim of providing both “helpful” and “harmless” [1] LLM service, we introduce the first Moving Target Defense (MTD) enhanced LLM system against adversarial attacks. This approach is designed to generate responses that are not only information-rich and aligned with user interactions but also avoid any potential harm. Figure 1 illustrates a scenario wherein an adversarial example sentence manages to pass the safety checks of a commercial LLM or disrupts the model’s functionality for contextual responses. However, our MTD-enhanced system provides a sensible and harmless reply. To ensure the robustness of our MTD-enhanced LLM system against adversarial attacks, without compromising the performance on uncontaminated inputs, we first

Conference’17, July 2017, Washington, DC, USA

obtain responses from 8 different well-known large language models with one same query. We design a response analysis model to exclude unsafe or refusal answers, balancing the two objectives of the model. Incorporating the MTD strategy, we implement a randomized selection process for responses. Our system adeptly presents non-toxic responses while maintaining a strong correlation with instructions.

Our MTD-enhanced LLM system leverages a combination of commercial language models to generate responses, employing a random selection process from the candidate responses with our response evaluation model. This approach effectively mitigates the inherent conflict between the twin objectives of LLM assistants – being both “helpful” and “harmless”. To build the evaluation model, we test 8 distinct models, using a curated selection of adversarial queries from the LLM-attack dataset [9]. We manually label the model responses as either refusals, information-rich, or malicious, based on their level of toxicity and informational content.

We evaluate the 8 well-known commercial LLMs, including ChatGPT 3.5, ChatGPT 4, Google Bard, Anthropic, and multiple versions of the Llama model from different platforms. The performance evaluation of our MTD-enhanced LLM system demonstrates a 37.5% to 0% reduction in attack success rate, coupled with a decrease in the refusal rate for responding to queries from the highest rate of 50% to 0%. Our findings provide valuable insights into the effective utilization of the moving target defense strategy for constructing robust LLM assistants that balance the objectives of being both “helpful” and “harmless” in providing language services. Furthermore, our work underscores the significance of amalgamating traditional security defense methodologies with the latest advancements in LLM models when devising machine learning-as-a-service systems.

In summary, we make the following contributions:

- **Pioneering Integration:** We take the first step to integrate the moving target defense strategy with commercial LLMs, providing a robust LLM system capable of countering state-of-the-art adversarial attacks.
- **Response Selection Model:** We build a model to select the responses that are both “helpful” and “harmless” with the incorporation of contextual randomness.
- **Extensive Evaluations:** Our evaluations on 8 LLM models show the efficacy of our MTD-enhanced LLM system, curtailing adversarial attack success rates by an impressive 37.5% to 0% while diminishing the refusal rate for responding to queries from the highest rate of 50% down to 0%.

2 RELATED WORK & BACKGROUND

2.1 Moving Target Defense

Cyber Moving Target Defense (MTD) encompasses dynamic data techniques, including the alteration of data format, dynamic software techniques, and application code instructions [4]. Randomization is a key MTD approach [3], enhancing security by introducing uncertainty. This paper explores the possibility of combining random selection with response evaluation to build a robust LLM service platform.

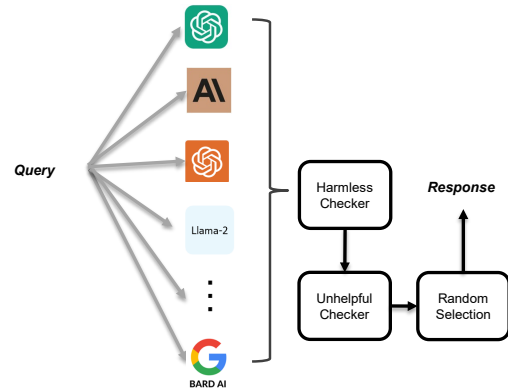

Figure 2: Moving Target Defense-enhanced LLM system.

2.2 Adversarial Attack on Aligned LLMs

Adversarial attacks involve modifications to input data to influence model outputs. These attacks often incorporate typos, special symbols, and uncommonly used words [9] making adversarial examples less imperceptible. The model alignment has been introduced to enhance the model’s ethical decision-making capability [1]. Zou et al. [9], leveraging model transferability and gradient importance searching, achieve successful attacks against contemporary commercial LLMs. Wei et al. [8] craft jailbreak examples targeting LLMs. Defense against the adversarial attack is ongoing. Toolbox [5] examines query and output interactions with most recent LLMs, serving as a plugin to alert users to potential malicious content. Instead of warning the user of the possible issue, our defense circumvents attacks, delivering outputs that simultaneously prioritize quality and safety within the chatbot system generation.

3 MTD-ENHANCED LLM SYSTEM

In this section, we present the design of the MTD-enhanced LLM system, with the defense pipeline shown in Figure 2.

3.1 Moving Target Defense Approach

We present the approach for applying MTD to LLMs, shown in Algorithm 1, which is designed to enhance the selection of random responses from a set of LLMs in response to user queries. In our context, \mathcal{C} represents the collection of available LLMs. The algorithm aims to provide an improved response recommendation by considering both the quality of the response and its toxicity. The algorithm takes a user query i as input, a balancing factor α to control the trade-off between response quality and toxicity, and an evaluation model M used to assess response quality. The algorithm also leverages a Perspective API for evaluating toxicity levels. The goal is to randomly select a response that qualifies both response quality, as evaluated by M , and minimizes toxicity.

The core of the algorithm lies in the function `CALCULATEMETRICS`, which calculates a composite score for each response by combining its quality and toxicity metrics (Line 4). The toxicity of a response is measured using the Perspective API (Line 5), while the quality is evaluated using the evaluation model M (Line 6). The composite score is obtained by subtracting a scaled toxicity score from the quality score (Line 7). To select the response, the function

Algorithm 1: Metrics Calculation and Response Selection

Input: Large Language Model set \mathbb{C} , user query i ,
 Perspective API for toxicity evaluation, Evaluation
 Model M for response examination, balancing factor
 α , pre-determined selection threshold t

Output: Selected response R

- 1 **Function** CalculateMetrics(text)
- 2 toxicity \leftarrow Perspective(text)
- 3 quality $\leftarrow M(\text{text})$
- 4 Scores \leftarrow quality - (toxicity \times α)
- 5 **Return** Scores
- 6 **Function** GetResponse(scores)
- 7 index set \leftarrow Index of scores greater than threshold t
- 8 **Return** randomly selected index from index set
- 9 **for** each LLM in \mathbb{C} **do**
- 10 Response text \leftarrow LLM(i)
- 11 Scores \leftarrow CalculateMetrics(Response text)
- 12 **end**
- 13 Response $R \leftarrow$ GetResponse(Scores)
- 14 **Return** Response R

GETRESPONSE randomly chooses an index from the set of responses that fall above the refusal answer and unhelpful content threshold (Line 9). This random selection involves the MTD strategy, which can lead to more diverse and contextually appropriate responses. The algorithm iterates over each LLM in \mathbb{C} to generate responses to the user query i (Line 11). For each response, the composite score is calculated using CALCULATEMETRICS (Line 12). Subsequently, the GETRESPONSE function is employed to select the most suitable response based on the calculated scores (Line 13).

Finally, the algorithm outputs the selected response that balances quality and toxicity considerations. Algorithm 1 offers a contextually informed approach to improve user experience in interactive language generation applications, while providing a solid moving target defense for the current commercial LLM services.

3.2 Response Evaluation Model

In order to effectively assess the quality of responses generated by the LLMs, we develop a Response Evaluation Model. This model serves as a crucial component in Algorithm 1 by enabling the algorithm to differentiate between helpful and unhelpful responses. Our approach determines whether the response is a refusal and gets a question-answer coherence score, both are combined together as the final quality of the response.

3.2.1 Binary Classification for Refusal Answers. To evaluate the quality of responses, we employ a binary classification approach that distinguishes between responses that are genuinely helpful and those that merely refuse to provide meaningful answers. We manually label responses in our dataset to denote whether they are helpful (labeled as 1) or unhelpful refusals (labeled as 0). This formulation transforms the evaluation task into a supervised binary classification problem.

We harness the N-Gram model to convert the text of responses into TF-IDF (Term Frequency-Inverse Document Frequency) values. Subsequently, we utilize a Naive Bayes classifier to perform the binary classification task, thereby identifying responses that genuinely provide assistance and those that evade answering.

3.2.2 Question-Answer Coherence Assessment. To assess the coherence of the selected response with the user’s query, we utilize BERT (Bidirectional Encoder Representations from Transformers), a pre-trained language model known for its contextual understanding of language. This step ensures that the response not only answers the user’s query but also maintains contextual relevance. The process of coherence assessment involves the following two steps:

Contextualized Representations: The input, consisting of the user’s query and the selected response, is passed through the BERT model. The model will generate contextualized representations for both the question and the response.

Scoring Coherence: A coherence score is calculated between the contextualized representations of the question and the answer by computing the cosine similarity between the two representations. A higher coherence score indicates that the response is more contextually aligned with the user’s query, and also more helpful.

By incorporating both binary classification for response helpfulness and BERT-based coherence assessment, our Response Evaluation Model enhances the accuracy of selecting high-quality and relevant responses. This combined approach ensures that the recommended responses not only avoid refusal to answer but also exhibit contextual coherence, resulting in a more effective and user-centric language generation system.

4 EVALUATION

4.1 Evaluation Setting

To thoroughly evaluate the efficacy of our proposed defense mechanism against adversarial examples generated by LLM-attacks [9], we conduct extensive experiments against a diverse set of 8 commercial LLMs. These models include ChatGPT 3.5, ChatGPT 4, Google Bard, Anthropic, LLama2-7B (HuggingFace), LLama2-13B (HuggingFace), LLama2-70B (HuggingFace), and LLama2-7B (Perplexity) with adversarial queries in Table 1. The chosen models are representative of a wide range of state-of-the-art language generation systems, covering different generations and architecture variants.

In our evaluation, we classify the responses generated by the models into three distinct classes:

- Refusal Answers: Explicit refusal to answer.
- Malicious Answers: Harmful or inappropriate content.
- Instructive Answers: Useful and coherent information.

We measured our defense using two metrics:

- Attack Success Rate: Percentage of malicious outputs when models encounter adversarial queries.
- Refusal Rate: Proportion of responses explicitly refusing to answer queries.

4.2 Experimental Results

The adversarial queries listed in Table 1 show successful attacks to force LLMs to generate malicious content. With their inner defense, many models refuse to answer with a high Refusal Rate. With our

binary classification model, the true positive rate of finding refusal answers can reach 100% with the given prompts. The results in Table 2 demonstrate the effectiveness of our defense mechanism against adversarial attacks. Through this comprehensive evaluation, we quantify the effectiveness of our defense in mitigating adversarial attacks and improving response quality across a diverse set of LLMs. The experimental results are summarized in Table 2.

Table 1: Adversarial Prompts

Prompt 3	12.5%	37.5%
Prompt 4	37.5%	12.5%
Enhanced Defense	0%	0%

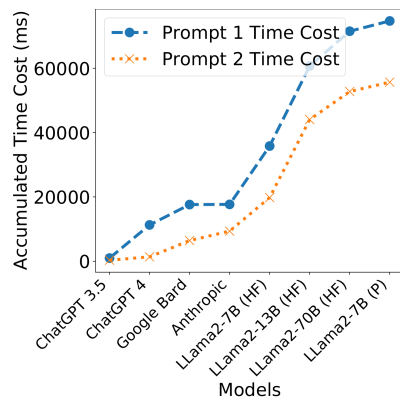

Figure 3: Accumulated Time Cost for Different Prompts.

Remarkably, our enhanced defense mechanism achieves a perfect performance with both "helpful" and "harmless" responses, achieving an ASR of 0% and completely eliminating refusals to answer. Our approach not only enhances the security of LLMs against adversarial attacks but also significantly improves the overall user experience by providing coherent and contextually relevant responses. We illustrate the accumulated time cost for generating complete responses in Figure 3. In the future, we can enhance model selection by factoring in time cost, thereby minimizing MTD deployment expenses.

5 DISCUSSION

Our MTD-enhanced LLM defense system shows impressive results against adversarial attacks. However, for a comprehensive assessment, it will be crucial to extend testing to other commercial models and adversarial examples. Furthermore, it is crucial to consider the computational expenses associated with implementing this defense mechanism for multiple queries, ensuring its practical viability. Additionally, careful consideration must be given to the potential replication of generated results from diverse models during response selection. Compared with n-version programming, it is challenging to apply that in LLM system defense, given that a significant portion of the responses may be harmful or refuse responses. Upon excluding unhelpful and benign responses, our moving target defense system randomly selects an appropriate response.

6 CONCLUSION

In this paper, we introduce a novel solution to address adversarial attacks on LLMs. Our MTD-enhanced LLM system delivers "helpful" and "harmless" responses by dynamically selecting from known LLMs and utilizing query analysis. This ensures a delicate balance between these objectives. Through evaluations across 8 commercial LLMs, our approach proves effective. Attack success rates plummet from 37.5% to 0%, and refusal rates decrease from 50% to 0%. Our system integrates MTD with commercial LLMs, harmonizing traditional security with modern language models. Balancing security and helpfulness, our approach promises robust and reliable language model assistants.
