Abstract

Super-Resolution (SR) is a time-hallowed image processing problem that aims to improve the quality of a Low-Resolution (LR) sample up to the standard of its High-Resolution (HR) counterpart. We aim to address this by introducing Super-Resolution Generator (SuRGe), a fully-convolutional Generative Adversarial Network (GAN)-based architecture for SR. We show that distinct convolutional features obtained at increasing depths of a GAN generator can be optimally combined by a set of learnable convex weights to improve the quality of generated SR samples. In the process, we employ the Jensen–Shannon and the Gromov-Wasserstein losses respectively between the SR-HR and LR-SR pairs of distributions to further aid the generator of SuRGe to better exploit the available information in an attempt to improve SR. Moreover, we train the discriminator of SuRGe with the Wasserstein loss with gradient penalty, to primarily prevent mode collapse. The proposed SuRGe, as an end-to-end GAN workflow tailor-made for super-resolution, offers improved performance while maintaining low inference time. The efficacy of SuRGe is substantiated by its superior performance compared to 18 state-of-the-art contenders on 10 benchmark datasets.

I. INTRODUCTION

A Low Resolution (LR) image sacrifices information of its High Resolution (HR) counterpart in favor of general utility such as displaying or editing in smaller screens, low storage requirement, and fast transmission. Super-resolution attempts to recover the original HR copy from a LR input. However, the initial HR to LR transformation is commonly non-invertible and lossy [1]. Thus, recovering the HR by estimating a Super Resolution (SR) analog is an ill-posed problem that contains the risk of a distorted output [2].

The classical interpolation methods for super-resolution only exploit local information and are thus incapable of generating commendable SR [3]. While global image features extracted by the deep convolutional networks translate to a much improved performance [4], [5] limited generalizability and distorted SR still remain as major concerns [6].

The landscape of super-resolution techniques had a major breakthrough with the advent of the Generative Adversarial Network (GAN) [7]. A super-resolution GAN [8] embraces the canonical two-player adversarial game between a generator G and a discriminator D with some minor modifications. Specifically, in a super-resolution task, G attempts to map a LR input to a HR ground truth, generating an estimated SR in the process. The discriminator D helps G by providing adversarial feedback through distinguishing between a HR ground truth and G generated SR. While GAN-based super-resolution offers generalizability through their generative power they often have SR outputs that lose finer details or are plagued by artifacts [9], [10].

In this paper, we propose a GAN-based super-resolution method called <u>Super-Resolution Generator</u> (SuRGe). In a superresolution task, to generate a good quality SR image, it is necessary to consider both the low-level local features (for example, colors, textures, edges, etc.) and the high-level global ones (such as individual object shapes, relative positioning of objects and background, object orientation, etc.). As noted in [11], [12], higher-level global features are progressively captured by convolutional filters residing deeper in the network. Taking inspiration from [11], [13] in the generator G of the proposed SuRGe, we preserve the hierarchically complex features and dictate their flow through skip connections. However, skip connections may lead to under-utilized network capacity [14] while a potential solution like DenseNet may be challenging to train [15] with limited data. Therefore, in SuRGe, we design a generator G that judiciously uses the skip connections to conserve and propagate only a few selected features that are intuitively more useful for improving the network's performance on superresolution task (for example, carrying forward the low-level features to recover minute details after a potentially distortion inducing up-sampling step, in a spirit similar to that of UNet [13]). To adaptively combine the features coming from different depths of the network we introduce mixing modules that operate in a learnable fashion.

We further focus on the fact that ideally the distributions of SR and HR should be identical. Thus, a loss function like Jensen–Shannon (JS) divergence that explicitly encourages minimizing the dissimilarity between the respective distributions of

Fig. 1: Visual comparison of 4x super-resolution outputs of the proposed SuRGe with SRGAN [8], BSRGAN [16], SWIN-IR [17], and LTE [18], given a low-resolution (LR) input image patch. SuRGe is producing better super-resolution images with finer texture, color, and intricate details.

HR and SR, helps in training the generator G in SuRGe. Moreover, in the ideal case, LR and SR should also preserve structural similarities, which consequently gets reflected in their corresponding distributions. However, LR and SR reside in different metric spaces with potentially distinct dimensionality. Thus, to explicitly minimize the discrepancy between the respective distributions of LR and SR we further utilize the Gromov Wasserstein (GW) distance [19] as an additional loss function in the generator G of SuRGe. As per our knowledge, this is the first time the applicability of explicit divergence measures is explored in the context of GAN-based super-resolution techniques. We also employ a dynamically weighted convex combination strategy of the multiple losses in G [20] of SuRGe. Furthermore, to prevent G from mode collapsing, especially on the smaller training sets used in super-resolution [21] we employ Wasserstein loss with gradient penalty (WGAN-GP) [22] to train the discriminator D in SuRGe.

The primary contributions of our fully-convolutional GAN-based SR method SuRGe are as follows.

- To the best of our knowledge, SuRGe is the first super-resolution model that introduces GW, a divergence between metric spaces of potentially different dimensions, to fuel the learning of generator G. This incorporation of LR-SR relationship directly endows SuRGe with authentic super-resolution capabilities.
- Moving away from pre-trained model-biased perceptual similarity, SuRGe takes JS divergence as an additional loss of generator G (alongside adversarial and GW) while discriminator D uses gradient penalized Wasserstein loss to improve the SR.
- We introduce a generator G in SuRGe that efficiently employs skip connections to garner semantic information from different levels of feature representation and supports their adaptive mixing in a learnable fashion.

The effect of these critical improvements is evident in the motivational example in Figure 1, where compared to four notable contenders, the SR obtained by SuRGe is richer in finer details and most closely matches the HR. Following a brief review of the existing deep super-resolution strategies using Convolutional Neural Networks and Transformers in Section II, we detail the proposed methodology in Section III. In Section IV we show that the proposed SuRGe outperforms the current best by an average of 3.51% and 5.45% respectively in terms of PSNR [23] and SSIM [24] on four common benchmarks for 4x super-resolution. Further, SuRGe supersedes the state-of-the-arts by 15.19% in terms of PSNR on six complex 4x super-resolution datasets.

II. RELATED WORKS

Deep super-resolution models can be Convolutional Neural Networks (CNNs), GANs, and, more recently transformers. The CNN-based methods are the first to employ deep networks for super-resolution [6], using convolution maps through the image followed by interpolation methodologies similar to a typical convolutional autoencoder. Though innovative for initial study and duly credited for a remarkable improvement over the traditional techniques, such CNN architectures suffer from poor generalizability and thus are domain-dependent [4]. As a remedy, WDRN [25], employs distinct wavelet features and their adaptive mixture for a better super resolution performance.

The shortcomings of CNN can be addressed using GANs [8] with task-specific modifications. This route of research mainly diverges into three primary avenues. First, removing normalization and introducing dense blocks in generator [26], indeed improve the SR image quality although with a greater computational cost. Second, replacing dense networks with residual backbone [27] utilizing skip connections. Even though, such networks are considerably easier to train, their full potential may not be realized without carefully curating the skip connections and feature mixing that best aids the super-resolution task. Third, additional preprocessing such as blurring and specialized noise injection [16], [28] produces augmentations that are close to real-life scenarios and can lead to more enhanced SR output. Unfortunately, this also purposefully distorts the input distribution that may in turn sacrifice the clarity and details. On the other hand, considering perceptual similarity is introduced in [29] that directly depends upon the generalization of an external pre-trained network for optimizing the generator. In summary, such methods typically suffer from loss of minute details [16] or distorted boundaries [29]. Moreover, all of these methods perform the required up-scaling at once at the end of the network. Thus, any possible distortion during the drastic up-scaling cannot be mitigated by the network. Furthermore, the ever-improving GAN variants remain mostly unexplored in the context of super-resolution.

SAN [30] introduces channel attention in CNN to open the gate for transformer networks in super-resolution. In support of a better performance, transformers not only manage to adaptively mix diversely informative features through attention [17], [31] but also mitigate SR output distortions using layer normalization. In [32], the idea of cross-attention is proposed which was later improved in [33] to mitigate the adverse impacts of uncontrolled mixing of distinct features. The DAT [34] introduces a novel transformer model that aggregates features through inter-block spatial and intra-block channel attentions. In essence, they introduce Adaptive Interaction Module (AIM) and the Spatial-Gate Feed-Forward network (SGFN) for a tailored feature aggregation at different level. Later, SR-Former [35] attempts to improve [34] by focusing on Permuted Self Attention (PSA) for a more balanced approach towards feature aggregation through channel and spatial attentions.

III. PROPOSED METHOD

Typically, image matrix (or vector if flattened) resides in lower-dimensional ambient space \mathcal{M}_1 [36] i.e. a low-resolution (LR) image $\mathbf{x} \in \mathcal{M}_1$. Thus, a higher-resolution (HR) version of \mathbf{x} exists as $\mathbf{y} \in \mathcal{M}_2$ that improves definition. The estimated form of \mathbf{y} is known as the super-resolution output SR. Commonly $\mathcal{M}_1 \subset \mathbb{R}^{whc}$ and $\mathcal{M}_2 \subset \mathbb{R}^{w'h'c}$, where w' = wr, h' = hr, and $r \in \mathbb{Z}^+$ is the multiplicative scaling factor [37] denoting the extent of magnification from LR to HR (or SR). A GAN-based super-resolution method given input \mathbf{x} searches for a generator $G \in \{G_\theta : \mathcal{M}_1 \to \mathcal{M}_2 | \theta \in \Theta\}$ that minimizes the discrepancy between SR $G(\mathbf{x})$ and its HR analog \mathbf{y} . A discriminator D guides G by providing feedback through distinguishing \mathbf{y} and $G(\mathbf{x})$. We further denote the distributions of LR, HR, and SR as $p_{\mathbf{x}}$, $p_{\mathbf{y}}$, and $p_{G(\mathbf{x})}$ respectively.

A. The Architecture of G

The generator G aims to recover y from x under the commonly used constraint of r = 4 i.e. through 4x super-resolution [6], [8], [17], [26], [32]. Unlike popular practice [17], [32] of performing 4x up-scaling in one shot at the end, G in SuRGe performs the same in two steps i.e. a 2x up-scaling (see Figure 2) at the end of each half. This way, the right half of G can mitigate the possible abrupt distortions of the feature space due to the first 2x up-scaling and reuse features from the left half (through skip connections) to recover corrupted information. We demonstrate G in Figure 2 highlighting the key components while detailing them individually in the following.

The initial convolution block (C_0) extracts the low-level features using larger kernels with half-padding, providing two benefits. (1) Repetitive information and their variation over a larger region can be better captured [38]. (2) Possible distortions near the image boundaries can be avoided [6]. Moreover, we use parametric ReLU to allow the distinct layers to have different non-linearity for better conservation of low-level features. Further, we discard normalization to avoid information loss through regularization and scaling.

The repetitive residual generator block (R_0) focus on extracting high-level intricate features using smaller kernels. This contains n_G residual blocks [11], each having two sub-blocks. The first sub-block alone uses parametric ReLU activation while both employ batch normalization to induce regularization and limit covariance shift. The outputs of the two sub-blocks are added through a skip connection and passed to the next residual block. The inter-sub-block skip connection ensures that the features after each convolution and normalization at least retain the extracted information, if not able to enrich it further.

The n_G -th block of R_0 sums the outputs of its two sub-blocks. This distorted feature space, similar to a typical ResNet, must be further stabilized before being processed in the next stage. However, the common remedy of average pooling fails in super-resolution because neither such a kernel is learned nor the down-scaling goes along with the task objective. Therefore, the intermediate convolution block (I_0) is added to stabilize the output of R_0 by additional convolutions with batch normalization.

At the outputs of C_0 and I_0 , we respectively have low and high level features. Thus, we use the first weighted feature mixing module F_0 to combine these two features before up-scaling. F_0 performs a simple convex combination as:

$$F_0 = w_1^{(F_0)} C_0 + w_2^{(F_0)} I_0(R_0(C_0)), \tag{1}$$

Fig. 2: The schematic of SuRGe demonstrates two of its main components in (a) the generator G and (b) the discriminator D. Moreover, in (c), we detail the structure of our sub-network Repetitive Residual Block used in G and D. G takes a LR image \mathbf{x} and generates a 4x up-scaled SR image $G(\mathbf{x})$. D guides G by distinguishing an input between HR ground truth \mathbf{y} and SR $G(\mathbf{x})$. Further details on network design can be found in the A.

Fig. 3: In comparison to HR patch (a) of a butterfly image, the checkerboard pattern introduced by PixelShuffle [9] is apparent in (b). Nearest neighbor up-scaling in SuRGe generates clean $G(\mathbf{x})$ as evident from our result in (c).

where $w_1^{(F_0)}, w_2^{(F_0)} > 0$ and $w_1^{(F_0)} + w_2^{(F_0)} = 1$. We learn both of $w_1^{(F_0)}$ and $w_2^{(F_0)}$ as parameters of G while the convexity constraint is ensured by passing the weights through a Softmax activation.

The output of F_0 is first stabilized with convolution and then passed to U_0 for 2x up-scaling. The commonly used up-scaling techniques such as PixelShuffle and transposed convolutions, though effective otherwise, are likely to distort SR as in Figure 3. This is because the overlapped kernels may introduce uneven convolution that results in higher frequency color patterns like a checkerboard in the border pixels of the kernel mapping. Hence, we employ the interpolation-based nearest neighbors method [1] for up-scaling.

Except for F_1 , the rest of the right half of G is identical to the left. The right or second half of G starts with an initial convolution layer C_1 that stabilizes the U_0 output. In an attempt to recover any lost or corrupted information at this stage, we

add the output of C_1 with the 2x up-sampled output of C_0 after passing it through a skip block S. The sum is then propagated through R_1 and I_1 layers. F_1 takes the following three inputs: (1) C_0 output 2x up-scaled by a skip block S having a structure similar to $U \circ C$ that recovers the low-level features at the end of the network. (2) The output of I_1 . (3) The output of C_1 . Similar to F_0 here also we perform a convex combination of the three inputs as follows:

$$F_1 = w_1^{(F_1)} I_1 + w_2^{(F_1)} C_1 + w_3^{(F_1)} S(C_0),$$
(2)

where the three weights $w_1^{(F_1)}$, $w_2^{(F_1)}$, and $w_3^{(F_1)}$ are constrained with convexity similarly to their counterparts in F_0 and are thus learned in the same way. The output of F_1 is 2x up-scaled by U_1 , and stabilized by further convolutions (without batch normalization or activation to avoid distortion) to produce the SR output $G(\mathbf{x})$.

B. The Architecture of D

As demonstrated in Figure 2, D has two main components: a sub-network called Repetitive Residual Discriminator Block B and a classification head H. The structure of B mostly follows R as it contains n_D residual blocks, each with two sub-blocks connected by an inter-sub-block skip connection. Maintaining near structural similarity between G and D enables the same input to likely have close embeddings in the learned feature space. Thus, D can easily identify a deviation of $G(\mathbf{x})$ from \mathbf{y} and improve G through a more useful feedback.

There are three key differences between R and B. (1) B uses LeakyReLU activation to prevent sparse or scattered gradients [7]. (2) B employs Pixel normalization [39], as batch normalization is known to cause quality issues in a super-resolution task when used in D [10], [26]. (3) The number of filters and the convolution kernel size are gradually increased over the residual blocks. This not only improves the balanced capture of low-level and high-level information but also prevents over-fitting by removing bias to a particular kernel size.

The classification head H first performs an adaptive average pooling on the output of B. The pooled features are then flattened and passed through dense layers with LeakyReLU activation. The final dense layer maps the features to a single node and applies Sigmoid activation on the logit to find the probability of the input being HR ground truth.

C. Loss functions of SuRGe

SuRGe, embodying the GAN philosophy, has tailor-made losses for the generator G and the discriminator D. 1) Loss for generator G:: To receive guidance from D, G utilizes a traditional adversarial loss \mathcal{L}_a^G defined as:

$$\mathcal{L}_{a}^{G} = -\sum_{\mathbf{x}\in N} \log D(G(\mathbf{x})), \tag{3}$$

where N is a training batch.

The classical \mathcal{L}_a^G , though necessary, is not sufficient for maintaining the desired perceptual quality of the SR output, when deployed alone. A common remedy [8], [27] is to additionally minimize the discrepancy between HR and SR in the embedding space of a pre-trained deep network that is likely capable of expressing perceptual information. Evidently, the efficacy of such a loss is reliant on the quality and generalizability of the pre-trained embedding space [26]. However, p_y and $p_{G(x)}$, respectively the distributions of HR and SR, in practice are supported on the same ambient space. Hence, directly minimizing their divergence using a symmetric measure like JS motivates G(x) to resemble y:

$$\mathcal{L}_{\mathrm{JS}}^{G} = \frac{1}{2} \mathbb{E}_{p_{\mathbf{y}}} \left[\log(p_{\mathbf{y}}) - \log\left(\frac{(p_{\mathbf{y}} + p_{G(\mathbf{x})})}{2}\right) \right] + \frac{1}{2} \mathbb{E}_{p_{G(\mathbf{x})}} \left[\log(p_{G(\mathbf{x})}) - \log\left(\frac{1}{(p_{G(\mathbf{x})} + p_{\mathbf{y}})}2\right) \right]. \tag{4}$$

As the name suggests, at the heart of the super-resolution problem lies the task of learning a meaningful transformation G that refines LR images visually. The optimization, however, is constrained based on the need to preserve semantic features. Such information in a set of samples is stored not only in coordinate entries of the vectors but also into their local geometry. As such, a generative model becomes a true SR architecture on the basis of its capacity to keep the metric measure spaces corresponding to p_x and $p_{G(x)}$ near-isometric. The divergence that enables penalizing the deviation from such an ideal scenario is GW. Thus in SuRGe, we integrate the GW loss in training G:

$$\mathcal{L}_{\text{GW}}^{G} = \min_{\gamma \in \Gamma} \int |d_1(\mathbf{x}, \tilde{\mathbf{x}}) - d_2(\mathbf{z}, \tilde{\mathbf{z}})|^2 d\gamma(\mathbf{x}, \mathbf{z}) d\gamma(\tilde{\mathbf{x}}, \tilde{\mathbf{z}}),$$
(5)

where Γ is the set of couplings between distributions $p_{\mathbf{x}}$ and $p_{G(\mathbf{x})}$, while $\mathbf{x}, \bar{\mathbf{x}} \sim p_{\mathbf{x}}$, and $\mathbf{z}, \bar{\mathbf{z}} \sim p_{G(\mathbf{x})}$. Also, d_1, d_2 are the metrics on the spaces \mathcal{M}_1 and \mathcal{M}_2 respectively.

Tuning a set of static weights to combine the three loss components in \mathcal{L}_G is not only tedious but also inefficient due to being oblivious to dynamic training situations. Learning the weights as network parameters may also bias the training towards a particular component. Thus, we employ a convex combination of the three loss components where the weights are dynamically calculated [20]. Specifically, the values of the three loss components are passed through Softmax. As such, the dynamically

assigned weight to a loss component depends on its value such that at any point in time, the weights adjust according to the values for preventing the dominance of one on the others in the combined \mathcal{L}^G . In essence, at each iteration of training:

$$\mathcal{L}^{G} = w_{a}\mathcal{L}^{G}_{a} + w_{JS}\mathcal{L}^{G}_{JS} + w_{GW}\mathcal{L}^{G}_{GW}, \text{ where } w_{(\cdot)} = \frac{\exp(\mathcal{L}^{G}_{(\cdot)})}{(\exp(\mathcal{L}^{G}_{a}) + \exp(\mathcal{L}^{G}_{JS}) + \exp(\mathcal{L}^{G}_{GW}))}.$$
(6)

Now $w_{(\cdot)}$ can be w_a , w_{JS} and w_{GW} while $\mathcal{L}_{(\cdot)}^G$ is respectively set to \mathcal{L}_a^G , \mathcal{L}_{JS}^G , and \mathcal{L}_{GW}^G . 2) Loss for discriminator D:: We draw inspiration from WGANs' promise of improving generation quality by deploying the Wasserstein-1 distance (WD) to distinguish between 'real' and 'fake' samples. The underlying class of critic functions (them being k-Lipschitz continuous) additionally mollify mode collapse [40]. However, maintaining k-Lipschitz continuity during training is difficult as it requires limiting the gradients of D. WGAN achieves this by a weight-clipping heuristic that sacrifices complexity. As a better alternative, WGAN-GP puts a constraint on the gradient itself that can be expressed as a regularizer called gradient penalty. Thus, \mathcal{L}^D can be written as follows:

$$\mathcal{L}^{D} = \mathbb{E}_{p_{\mathbf{x}}} D(G(\mathbf{x})) - \mathbb{E}_{p_{\mathbf{y}}} D(\mathbf{y}) + \lambda \mathbb{E}(||\nabla_{\hat{\mathbf{x}}} D(\hat{\mathbf{x}})||_{2} - 1)^{2},$$
(7)

where $\hat{\mathbf{x}} = \epsilon \mathbf{y} + (1 - \epsilon)G(\mathbf{x})$, and $\epsilon \sim \text{Uniform}(0, 1)$.

Fig. 4: We extract patch from HR as y and down-scale it to LR input x. The x is fed to G to obtain the 4x SR G(x). The $G(\mathbf{x})$ is used for \mathcal{L}_a^G using equation (3), $G(\mathbf{x})$ and \mathbf{y} together is used for \mathcal{L}_{JS}^G using equation (4), and \mathbf{x} with $G(\mathbf{x})$ find \mathcal{L}_{GW}^G using equation (5). We take the Softmax-based dynamic convex combination of \mathcal{L}_a^G , \mathcal{L}_{JS}^G , and \mathcal{L}_{GW}^G as per equation (6) to find \mathcal{L}^G to update G. For updating D, we use \mathbf{y} and $G(\mathbf{x})$ to calculate \mathcal{L}^D using equation (7).

D. Putting it all together

The workflow of SuRGe is illustrated in Figure 4 while the algorithm is described in Algorithm 1 in B. We follow a patch-based training [8], [37] in SuRGe. The idea is to extract 256×256 overlapped patch of the HR ground truth as y and

IV. EXPERIMENTS

A. Experimental Protocol

Following standard practice, we train SuRGe on DIV2K [21] dataset using the 800 training examples. We test SuRGe on four popular benchmarks namely Set5 [41], Set14 [42], BSD100 [43], and Urban100 [4] along with six additional datasets viz. Kitti2012, Kitti2015 [44], Middlebury [45], PIRM [46], OST300 [47] and MANGA109 [48]. The details of network architecture, datasets, pre-processing of input, the hyper-parameters choices, and their tuning with grid search are provided respectively in A, B, and D. We use PSNR [23] and SSIM [24] to measure the performances of all the methods both of which are described in B. The code for SuRGe is currently provided as a supplementary archieved file to this article, once accepted for publication the code-base will be uploaded to a public GitHub repository for ease of access and result reproduction.

B. Ablation study

We start with an ablation study of the five critical components in SuRGe, namely the choice of backbone in D, the kernel size for convolution in D, the choice of loss functions in G, the combination strategy of $F_{0,1}$ in G, and the loss function in D. Table I shows that over the seven intermediate models on the BSD100 dataset, the performance gradually improves in terms of PSNR and SSIM with better choices for the components. The best performance is achieved when all the components act in harmony, validating their importance in SuRGe. Moreover, previous uses of GW [49] argued in favor of representations obtained from a pre-trained deep network to limit the dimensions and improve stability. However, the particular task of super-resolution may benefit from the flattened images as that mitigate the risk of unregulated information alteration through feature extraction. We empirically confirm this through a comparison of V_3 and V_5 passing image features extracted from a pre-trained mages to the $\mathcal{L}_{\text{JS}}^G$ and $\mathcal{L}_{\text{GW}}^G$. Our experiment shows that using flattened images gives performance boost compared to ResNet-50 embedding space. As an extension, in Figure 5, we further show that the SR output generated by SuRGe progressively improves over training.

TABLE II: Performance comparison of SuRGe in terms of PSNR and SSIM on four benchmarks against notable competitors.

¹ Boldfaced: best, Underlined: second best. ² CNNA: CNN+Attention, TRAN: Transformer.

³ Increment indicates improvement.

C. Quantitative performance of SuRGe

In Table II we exhibit the efficacy of the proposed SuRGe on Set5, Set14, BSD100, and Urban100 benchmarks in terms of PSNR and SSIM. For comparison, we select 16 state-of-the-art methods from 4 groups. (1) CNN-based: SRCNN [6], SelfExSR [4], and DBPN-RES-MR64-3 [50]. (2) GAN-based: SRGAN [8], ProSR-L [37], ESRGAN [26], RankSRGAN [51], Beby-GAN [29], and GramGAN [52]. (3) CNN with attention-based: SAN [30] and WRAN [53]. (4) Transformer-based: SwinIR and SWIN-IR+ [17], LTE [18], SwinFIR [31], and HAT-L [33]. Table II shows that except Set5, on all the other datasets, SuRGe performs better in terms of both indices, attesting to its consistency. In terms of percentage points (pp), SuRGe improves the PSNR and SSIM metrics respectively with 1.89pp and 6.3pp, on average on Set14, BSD100, and Urban100. In Set5, even though SuRGe achieves the best SSIM jointly with the transformer-based SwinFIR, the PSNR is slightly lower than two competitors. This may be attributed to the exceptionally smaller LR images in Set5. Such LR image contains more intricate details in a lesser number of pixels. Consequently, the SR output of SuRGe retains most of the high-level visual similarity to attain a commendable SSIM, while the loss of some details is apparent from the slightly lower PSNR.

We further evaluate the efficacy of SuRGe on Kitti2012, Kitti2015, Middlebury, PIRM, OST300, and MANGA109. We compare the performance of SuRGe in terms of PSNR and SSIM in Table III against ten notable contenders viz. SRCNN, DBPN-RES-MR64-3, ESRGAN+ [27], SAN, RankSRGAN [51], NAFSSR-L [32], SwinIR+, SwinFIR, HAT [33], and HAT-L. We see from Table III that SuRGe achieves better PSNR and SSIM on all six datasets. This establishes the power of SuRGe in consistently generating better quality SR outputs.

D. Qualitative comparison

We compare the visual quality of SuRGe against BSRGAN [16], SRGAN, ESRGAN [26], Real-ESRGAN [28], LTE, and SwinIR in Figure 6. From Figure 6, we can make three key observations. (1) SRGAN, LTE, and SWIN-IR output comparatively

Dataset	Method	$PSNR(\uparrow)$	SSIM(†)
	ESRGAN+	24.15	
PIRM	RankSRGAN	25.62	
	SuRGe (Ours)	31.92	0.90
OST300	ESRGAN+	23.80	
031300	SuRGe (Ours)	31.01	0.86
	NAFSSR-L	27.12	0.82
Kitti2012	SwinFIR	26.83	0.81
	SuRGe (Ours)	32.31	0.88
	NAFSSR-L	26.96	0.82
Kitti2015	SwinFIR	26.00	0.80
	SuRGe (Ours)	31.12	0.89
	NAFSSR-L	<u>30.20</u>	0.85
Middleburry	SwinFIR	30.01	<u>0.86</u>
Middleburry	SuRGe (Ours)	35.72	0.93
	SRCNN	27.66	0.86
	DBPN-RES-MR64-3	31.74	0.92
	HAT-L	<u>33.09</u>	<u>0.93</u>
MANGA109	HAT	32.87	0.93
MAINGA109	SwinFIR	32.83	0.93
	SwinIR+	32.22	0.92
	SAN	31.66	0.92
	SuRGe (Ours)	34.17	0.95

TABLE III: Performance comparison of SuRGe in terms of PSNR and SSIM on six additional test datasets.

The best result is boldfaced, while the second best is underlined.

blurry SR than SuRGe. (2) ESRGAN and Real-ESRGAN, though preserve finer details may add more distortion and noise to SR. This is apparent from the mustache of the baboon, the eyebrow of the child, and the nails of the comic. (3) BSRGAN provides smooth, apparently attractive SR outputs but fails to conserve details to the limit of SuRGe. Thus, SuRGe produces better and more detailed SR outputs closer to the HR ground truths. Additional qualitative results along with quantitative support in favor of SuRGe can be found in D.

Fig. 6: A qualitative comparison of SR outputs generated by SRGAN [8], BSRGAN [16], ESRGAN [26], Real-ESRGAN [28], LTE [18], SWIN-IR [17] and SuRGe (Ours) in baboon (Set14), child (Set5) and comic (Set14) samples. The SR output of SuRGe is visually more similar to the HR ground truth for almost every patch for the three images.

V. CONCLUSION AND FUTURE WORKS

We propose a fully-convolutional GAN-based SuRGe that generates visually attractive 4x super-resolution images with minute details. SuRGe highlights the need for diversely informative feature preservation and their combination in a learnable fashion in super-resolution task. Further, possibly for the first time SuRGe successfully applies divergence measures such as GW as loss functions in the super-resolution context. Moreover, SuRGe demonstrates how the choices of kernel size, normalization methods, and the location and strategy of up-scaling impact the quality of the generated SR output. Furthermore, the commendable performance of SuRGe comes at a smaller model (in compariosn to GAN-based SR methods) with a low inference time, as shown in D. The use of divergence measures though considerably improves the performance of SuRGe they may also fall prey to noise present in the images, somewhat compromising the robustness in the process. This may be mitigated in the future by either exploring the applicability of robust divergence measures [54] or incorporating remedial techniques like median of means [55]. Moreover, the currently proposed architecture is tailored for 4x super-resolution as that is the most common and widely popular variant of the task. Generalizing the proposed model to a rx super-resolution where r is even, likely will not pose a significant challenge, though additional correction of up-sampled output may be required with increasing r. However, the case may become even more complicated if r becomes odd. A potential remedy can be in the form of a robust and adaptive up-sampling strategy that will incur minimal distortion and preferably operate in a self-correcting mode to enable a better super-resolution output.

DETAILED ARCHITECTURE OF THE SURGE NETWORK

Refer to Figure 7 and 8 for the detailed schematic description of the respective architectures of Generator G and Discriminator D in SuRGe.

A. Architecture of Generator

We present the architecture of Generator G in SuRGe. Taking a random LR patch from Baboon as an example input, the model constructed with $n_G = 8$ outputs a SR patch by passing it through different blocks as indicated by the legend.

Fig. 7: The architecture of G in SuRGe with the different individual components described in details.

B. Architecture of Discriminator

We demonstrate the discriminator model D of SuRGe in Figure 8. All blocks presented in the figure follows the same naming convention discussed in the Section III-B of the main paper. Discriminator D uses $n_D = 4$ along with a architecture of sub-blocks that is structurally similar to the generator G except the presence of normalisation. The classification head H is responsible for the distinguishing between real (HR) and fake (SR) image samples.

ALGORITHM OF SURGE

The following Algorithm 1 describes the workflow of SuRGe.

```
Algorithm 1 Super-Resolution Generator (SuRGe)
```

Input: $Y^{GT} = \{\mathbf{y}_1^{GT}, \mathbf{y}_2^{GT}, \dots, \mathbf{y}_m^{GT}\}$: training set of full HR Ground Truth (GT) images, N: mini-batch size, T: Number of epochs as a termination criterion. **Output:** A trained super-resolution image generator network G.

1: Initialize epoch counter t = 1. 2: 3: while $t \leq T$ do Initialize $Y = \phi$. for Each of $\mathbf{y}^{GT} \in Y^{GT}$ do 4: $Y = Y \cup \{\mathbf{y}\}$, where \mathbf{y} is a 256 × 256 patch, randomly extracted from \mathbf{y}^{GT} . 5: 6: end for 7: Sample $Y_N = {\mathbf{y}_1, \mathbf{y}_2, \cdots, \mathbf{y}_N} \subset Y$ of a batch of HR ground truth patches. Form $X_N = \{\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_N\}$ of LR training batch where \mathbf{x}_i is formed by down-scaling \mathbf{y}_i to 64×64 by bi-cubic interpolation for all $i = 1, 2, \dots, N$. Update G by gradient descent on $\mathcal{L}^G(X_N, Y_N, G(X_N))$. 8: 9: 10: Sample SR output batch $G(X_N) = \{G(\mathbf{x}_1), G(\mathbf{x}_2), \cdots, G(\mathbf{x}_N)\}$ where $\mathbf{x}_i \in X_n$. Update D by gradient descent on $\mathcal{L}^D(Y_N, G(X_N))$. 11: Increase epoch counter t = t + 1. 12 13: end while

Fig. 8: The architecture of D in SuRGe with a detailed description of the individual components is presented.

TABLE IV: Details of datasets

Dataset	Number of samples	Average ground truth resolution	Remark
DIV2K [21]	800	1971×1435	Only the training split is used to train SuRGe.
Set5 [41]	5	78×84	Benchmark, contains 5 samples in total.
Set14 [42]	14	112×101	Benchmark, contains 14 samples in total.
BSD100 [43]	100	110×89	Benchmark, contains 100 samples in total.
Urban100 [4]	100	246×199	Benchmark, contains 100 samples in total.
PIRM [46]	100	155×119	contains 100 samples from validation set.
KITTI2012 [44]	20	300×96	The same 20 samples are taken as in [32].
KITTI2015 [44]	20	300×96	The same 20 samples are taken as in [32].
Middlebury [45]	10	438×312	The same 10 samples are taken as in [32].
OST300 [47]	300	160×123	contains 300 samples in total.
MANGA109 [48]	109	207×300	contains 109 samples in total.

DESCRIPTION OF DATASETS

The following Table IV provides the details of the DIV2K training dataset [21] and the 10 benchmark testing datasets.

METRICS

We use two metrics to quantify and compare the performance of the super-resolution methods.

C. Peak Signal to Noise Ratio (PSNR)

PSNR [23] is a measure to quantify the noise present in an image compared to a reference. In case of super-resolution, if the ground truth is y and the SR output generated by G from a LR input x is G(x), then the PSNR (ρ) between the two is defined as:

$$\rho(\mathbf{y}, G(\mathbf{x})) = 20 \log_{10} \left[\frac{\max\{\mathbf{y}\}}{\frac{1}{wh} ||\mathbf{y} - G(\mathbf{x})||_2^2} \right],\tag{8}$$

where w and h respectively denote the width and height or \mathbf{y} or $G(\mathbf{x})$. Evidently, in equation (8) we want to decrease $||\mathbf{y} - G(\mathbf{x})||_2^2$ so that the SR output matches with the HR ground truth. In other words, a higher PSNR indicates a better quality SR.

D. Structural Similarity Index (SSIM)

SSIM [24] is another commonly used metric to compare an SR output to a reference HR ground truth. Similar to PSNR, given a SR output $G(\mathbf{x})$ and a HR ground truth \mathbf{y} the SSIM λ between the two is calculated as follows:

$$\lambda(\mathbf{y}, G(\mathbf{x})) = \frac{\left(2\mu_{\mathbf{y}}\mu_{G(\mathbf{x})} + c_{1}\right)\left(2Cov(\mathbf{y}, G(\mathbf{x})) + c_{2}\right)}{\left(\mu_{\mathbf{y}}^{2} + \mu_{G(\mathbf{x})}^{2} + c_{1}\right)\left(\sigma_{\mathbf{y}}^{2} + \sigma_{G(\mathbf{x})}^{2} + c_{2}\right)},\tag{9}$$

where, $\mu_{\mathbf{y}}$ and $\mu_{G(\mathbf{x})}$ are respectively the mean pixel values of HR ground truth and SR output, $\sigma_{\mathbf{y}}^2$ and $\sigma_{G(\mathbf{x})}^2$ denote the variance of pixel values in \mathbf{y} and $G(\mathbf{x})$, while $Cov(\mathbf{y}, G(\mathbf{x}))$ is the covariance between the pixel values of the two images. The two constants c_1 and c_2 ensure the non-zero property for the denominator and are usually kept to small values. A higher SSIM indicates the two images are more perceptually similar.

NETWORK ARCHITECTURE SELECTION BY GRID SEARCH

The grid search spaces and the final selected networks along with hyper-parameter settings for the generator G and the discriminator D in SuRGe are respectively detailed in Tables V and VI.

TABLE V: Grid search space with the selected G architecture and hyperparameter settings of SuRGe.

Block	Parameters	Grid search space	Final network
C_{0}, C_{1}	Kernel size (C_0, C_1) No. of convolutional filters (C_0) No. of convolutional filters (C_1) Stride (C_0, C_1) Padding (C_0, C_1) Activation (C_0, C_1) Normalization (C_0, C_1) Normalization technique (C_0, C_1) No. of convolution layers (C_0, C_1)		9 64 128 1 4 PReLU False 1
R_0, R_1	Inter-sub-blocks skip connection (R_0, R_1) No. of convolutions in sub-block (R_0, R_1) No. of convolution filters (R_0) No. of convolution filters (R_1) Kernel size (R_0, R_1) (Stride, Padding) (R_0, R_1) Activation presence in sub-blocks (R_0, R_1) Normalization in sub-blocks (R_0, R_1) Activation technique (R_0, R_1) Normalization technique (R_0, R_1)	True, False {1, 2} {32, 64} {64, 128} {3, 5} (1, 1) First, Second, Both First, Second, Both ReLU, LeakyReLU, PReLU BatchNorm, PixelNorm	True 1 64 128 3 (1, 1) First Both PReLU BatchNorm
I_0, I_1	Kernel size (I_0, I_1) No. of convolutional filters (I_0) No. of convolutional filters (I_1) (Stride, Padding) (I_0, I_1) Activation (I_0, I_1) Normalization (I_0, I_1) Normalization technique (I_0, I_1) No. of convolution layers (I_0, I_1)	{3,5} {32,64} {64,128} (1, 1) ReLU, LeakyReLU, PReLU True, False BatchNorm, PixelNorm {1,2}	3 64 128 (1, 1) PReLU True BatchNorm 1
U_0, U_1	Initial convolution present Kernel size of convolution (U_0, U_1) No. of convolutional filters (U_0) No. of convolutional filters (U_1) (Stride, Padding) (U_0, U_1) Activation (U_0, U_1) Normalization technique (U_0, U_1) No. of convolution layers (U_0, U_1) Up-scaling technique (U_0, U_1)	True, False {3, 5} {32, 64} {64, 128} (1, 1) ReLU, LeakyReLU, PReLU True, False {1, 2} Bi-cubic, PixelShuffle, NN*	True 3 64 128 (1, 1) PReLU False 1 NN
S	Structure similar to	$U_0 \circ C_1$	$U_0 \circ C_1$
Optimizer Adam	Learning rate (β_1, β_2)	{0.0001, 0.00025, 0.0005} (0.9, 0.99)	0.0001 (0.9, 0.99)

NN*: Nearest Neighbour method.

ADDITIONAL RESULTS

E. Inference time of SuRGe compared to recent GAN and Transformer-based contenders

To confirm if the several improvements made in SuRGe maintain a low inference time we compare the same in seconds against that of three recent GAN and transformer models viz. BSRGAN, SwinFIR, and LTE in the same computing setup. In essence, all algorithms are executed on a computing system with a single AMD Ryzen 9 3900x 12-core processor, one NVIDIA RTX 3090 24GB GPU, and a total of 64GB DDR4 memory. The following Table VII shows that on average on three datasets namely Set5, Set14, and BSD100, the proposed SuRGe provides good quality SR at the lowest inference time.

F. A comparison of performance vs. number of parameters for SuRGe and its notable GAN-based contenders

In the following Table VIII we provide a comparative study of performance (averaged over the four benchmark datasets viz. Set5 [41], Set14 [42], BSD100 [43], and URBAN100 [4], in terms of PSNR and SSIM) vs. the number of parameters (in millions) for GAN-based super-resolution techniques like the proposed SuRGe, PROSR-L [37], SRGAN [8], ESRGAN

Block	Parameters	Grid search space	Final network
С	Kernel size No. of convolutional filters (Stride, Padding) Activation Leakiness of LeakyReLU Normalization Normalization technique No. of convolution layers	{3,5} {32,64} (1, 1) ReLU, LeakyReLU, PReLU {0.1, 0.2} True, False {1, 2}	3 64 (1, 1) LeakyReLU 0.2 False 1

TABLE VI: Grid search space with the selected D architecture and hyperparameter settings of SuRGe.

TABLE VII: Average inference time in seconds for super-resolution of a single image. The best result is boldfaced and the second best is underlined.

Model	Set5	Set14	BSD100
BSRGAN LTE SwinFIR	$ \begin{array}{r} \underline{0.059} \\ 0.080 \\ 1.032 \end{array} $	0.095 0.132 1.886	<u>0.077</u> 0.099 1.389
SuRGe (Ours)	0.055	0.089	0.067
Speed-up of SuRGe from the current best model	1.07x	1.07x	1.15x

[26], BeByGAN [29], Rank-SRGAN [51]. We see from Table VIII that even though SuRGe uses about $2 \times$ parameters of PROSR-L it improves the PSNR with about 2.55 percentage points (pp) on average. Moreover, SuRGe and SRGAN use an almost similar number of parameters while the proposed outperforms the contender by about 4pp in PSNR and 13pp in SSIM. The rest of the competing methods use about 1.5x-2x parameters of SuRGe while achieving a lower PSNR and SSIM on average. Thus, SuRGe can be considered a comparatively lightweight GAN-based method that demonstrates high performance while maintaining a limit on the number of parameters.

TABLE VIII: Comparison of performance vs. the number of parameters for GAN-based approaches.

GAN-based Technique	No. of Parameters	Average Pe	erformance
	(in millions)	PSNR(†)	SSIM(†)
PROSR-L [37]	$ 13 (\approx 0.5 \times)$	27.78 (-4.33)	
SRGAN [8]	$25.1 (\approx 1 \times)$	26.19(-5.92)	0.75(-0.14)
ESRGAN [26]	$40 (\approx 1.5 \times)$	29.15(-2.96)	0.81 (-0.08)
BeByGAN [29]	$40 (\approx 1.5 \times)$	26.57(-5.54)	0.74(-0.15)
Rank-SRGAN [51]	53 (≈ 2×)	26.07 (-6.04)	0.65 (-0.24)
SuRGe (Ours)	25.7	32.11	0.89

Green indicates the number of parameters/performance of the contender is better than SuRGe. Red indicates the number of parameters/performance of the contender is worse than SuRGe. The ratio of the number of parameters and the difference in performance is measured considering SuRGe as a reference.

G. Simultaneous demonstration of qualitative and quantitative performances of SuRGe

Additionally, Figure 9 shows a qualitative performance comparison of SuRGe with five notable contenders namely SRGAN [8], BSRGAN [16], Real-ESRGAN [28], LTE [18], and SWIN-IR [17], on five test images viz. Cars (PIRM), Statues (BSD100), Balloons (PIRM), Horses (BSD100), and Lioness (OST300). For a simultaneous quantitative comparison we present the SSIM and PSNR values for the six algorithms on the five samples in Table IX. Figure 9 demonstrates how SuRGe maintains a higher degree of details in the SR output while the same is further quantitatively attested by the improved PSNR and SSIM in Table IX. Moreover, for the ease of visualization, a patch-based qualitative comparison is also presented in Figures 10 and 11 that enables focused observation on a particular region of the SR output.

Fig. 9: Additional qualitative performance comparison of SuRGe. The proposed SuRGe consistently produces SR outputs with finer details.

Method	Metric	Cars	Statues	Balloons	Horses	Lioness
SRGAN	PSNR	29.52	28.83	29.77	29.00	30.54
	SSIM	0.57	0.46	0.65	0.59	0.71
BSRGAN	PSNR	30.29	29.29	30.38	31.05	30.67
	SSIM	0.53	0.49	0.61	0.63	0.70
Real-ESRGAN	PSNR	30.38	29.10	30.32	30.92	31.08
	SSIM	0.58	0.48	0.65	0.62	0.70
LTE	PSNR	31.56	29.61	30.51	31.83	32.07
	SSIM	0.71	0.58	0.79	0.70	<u>0.79</u>
SWIN-IR	PSNR SSIM	$\frac{31.69}{0.72}$	$\frac{\underline{29.65}}{\underline{0.59}}$	$\frac{31.66}{0.81}$	$\frac{31.93}{0.72}$	<u>32.13</u> <u>0.79</u>
SuRGe (ours)	PSNR	34.21	32.79	32.31	33.13	34.74
	SSIM	0.82	0.79	0.86	0.86	0.91

TABLE IX: Additional quantitative performance comparison of SuRGe with the five contenders and five test samples used in Figure 9. The best is boldfaced while the second-best in underlined.

Fig. 10: We take three test samples, namely Cars (PIRM), Balloons (PIRM) and Statues (BSD100). We compare SuRGe with the contenders like SRGAN [8], BSRGAN [16], Real-ESRGAN [28], LTE [18], and SWIN-IR [17]. A patch-based visual comparison further aids us in clearly observing the greater amount of minute details (sunlight reflection on car headlight, eye details of the balloon toys, stone texture in statue) preserved by SuRGe in the SR output.

Fig. 11: In continuation of Figure 10 we take two more test samples namely Lioness (OST300) and Horses (BSD100) and compare the SR outputs of the same six methods. Here also, we see that SuRGe retains the finer details such as the fur of the lioness and her cubs, or the mane of the horses.
