We present the first search for the leptonic decays  $D^{*+} \rightarrow e^+ \nu_e$  and  $D^{*+} \rightarrow \mu^+ \nu_\mu$  by analyzing a data sample of electron-positron collisions recorded with the BESIII detector at center-of-mass energies between 4.178 and 4.226 GeV, corresponding to an integrated luminosity of  $6.32 \text{ fb}^{-1}$ . No significant signal is observed. The upper limits on the branching fractions for  $D^{*+} \rightarrow e^+ \nu_e$  and  $D^{*+} \rightarrow \mu^+ \nu_\mu$  are set to be  $1.1 \times 10^{-5}$  and  $4.3 \times 10^{-6}$  at 90% confidence level, respectively.

## I. INTRODUCTION

Experimentally, the study of pure leptonic decays of ground state charm mesons has entered the stage of precision measurement [1]. However, further exploration is needed for the pure leptonic decays of excited pseudoscalar mesons. The  $D^{*+}$  meson is the lightest excited state of the  $D^+$  meson, whose quark content is  $c\bar{d}$ , with a spin equal to 1.

In the Standard Model (SM), the leptonic decays  $D^{*+} \rightarrow \ell^+ \nu_\ell$  ( $\ell = e, \mu$ ) are described by the annihilation of the initial quark-antiquark pair into a virtual  $W^+$  that materializes  $\ell\nu_\ell$  pair as shown in Figure 1. Throughout this paper, charge conjugation is always implied, unless explicitly specified otherwise.

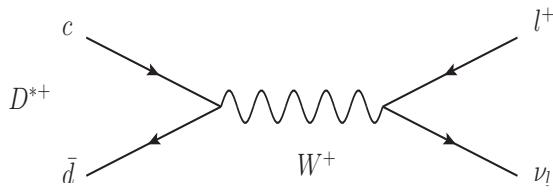

FIG. 1. Feynman diagram of  $D^{*+} \rightarrow \ell^+ \nu_\ell$ .

The examination of  $D^{*+} \rightarrow \ell^+ \nu_\ell$  decays holds significance, as their decay rates are linked to the Cabibbo-Kobayashi-Maskawa (CKM) matrix elements. The decay width of  $D^{*+} \rightarrow \ell^+ \nu_\ell$  can be parameterized by the  $D^{*+}$

decay constant  $f_{D^*}$  [2, 3] via

$$\Gamma = \frac{G_F^2}{12\pi} |V_{cd}|^2 f_{D^*}^2 m_{D^*}^3 \left(1 - \frac{m_\ell^2}{m_{D^*}^2}\right)^2 \left(1 + \frac{m_\ell^2}{2m_{D^*}^2}\right), \quad (1)$$

where  $G_F$  is the Fermi coupling constant,  $|V_{cd}|$  is the CKM matrix element between the  $c$  and  $d$  quarks, and  $m_\ell$  ( $m_{D^*}$ ) is the mass of the lepton ( $D^{*+}$ ). Several theoretical studies have anticipated the  $f_{D^*}$ , such as non-relativistic quark model, relativistic quark model, lattice QCD, etc., predicting  $f_{D^*}$  values between 186 MeV and 391 MeV [4]. In addition, as the  $D^{*+}$  can decay by the strong interaction, the branching fractions of these weak decays are at the  $10^{-10}$  level within the SM [3, 5, 6], but potential contributions from new pseudoscalar interactions beyond the SM could lift the branching fractions up to  $10^{-5}$  [7-9]. Any observation of the leptonic  $D^{*+}$  decays at a rate above the SM prediction would be a potential hint of new physics.

This paper reports the first searches ever performed for the leptonic decays  $D^{*+} \rightarrow e^+ \nu_e$  and  $D^{*+} \rightarrow \mu^+ \nu_\mu$ , using a data sample corresponding to an integrated luminosity of  $6.32 \text{ fb}^{-1}$ , recorded by the BESIII detector at center-of-mass (CM) energies ( $\sqrt{s}$ ) ranging from 4.178 to 4.226 GeV.

## II. DETECTOR AND DATA SETS

The BESIII detector [10] records symmetric  $e^+e^-$  collisions provided by the BEPCII storage ring [11], which

operates in  $\sqrt{s}$  from 2.00 to 4.95 GeV, with a peak luminosity of  $1 \times 10^{33} \text{ cm}^{-2}\text{s}^{-1}$  achieved at  $\sqrt{s} = 3.77$  GeV. BESIII has collected large data samples in this energy region [12]. The cylindrical core of the BESIII detector covers 93% of the full solid angle and consists of a helium-based multilayer drift chamber (MDC), a plastic scintillator time-of-flight system (TOF), and a CsI(Tl) electromagnetic calorimeter (EMC), which are all enclosed in a superconducting solenoidal magnet providing a 1.0 T magnetic field. The solenoid is supported by an octagonal flux-return yoke with resistive plate counter muon identification modules interleaved with steel (MUC) [13]. The charged-particle momentum resolution at 1 GeV/c is 0.5%, and the specific ionization energy loss ( $dE/dx$ ) resolution is 6% for electrons from Bhabha scattering. The EMC measures photon energies with a resolution of 2.5% (5%) at 1 GeV in the barrel (end-cap) region. The time resolution in the TOF barrel region is 68 ps, while that in the end-cap region is 110 ps. The end-cap TOF system was upgraded in 2015 using multigap resistive plate chamber technology, providing a time resolution of 60 ps [14].

The data samples used in this analysis are listed in Table I and provide a large sample of  $D^{*\pm}$  mesons from  $e^+e^- \rightarrow D^{*+}D^{*-}$  events with a cross section of about 3 nb [15].

TABLE I. Integrated luminosities  $\mathcal{L}_{\text{int}}$  [16, 17] of the data samples at different energies. The first and second uncertainties are statistical and systematic, respectively.

$\sqrt{s}$ (GeV)	$\mathcal{L}_{\text{int}}$ (pb $^{-1}$ )
4.178	$3189.0 \pm 0.2 \pm 31.9$
4.189	$526.7 \pm 0.1 \pm 2.2$
4.199	$526.0 \pm 0.1 \pm 2.1$
4.209	$517.1 \pm 0.1 \pm 1.8$
4.219	$514.6 \pm 0.1 \pm 1.8$
4.226	$1056.4 \pm 0.1 \pm 7.0$

Simulated Monte Carlo (MC) samples produced with GEANT4-based [18] software, which includes the geometric description of the BESIII detector and the detector response, are used to determine the detection efficiency and to estimate the background contributions. The simulation includes the beam-energy spread and initial-state radiation (ISR) in the  $e^+e^-$  annihilation modeled with the generator KKMC [19]. Inclusive MC samples of 40 times the size of the data samples are used to simulate the background contributions. The inclusive MC samples contain no signal decays and include the production of open-charm processes, the ISR production of vector charmonium(-like) states, and the continuum processes incorporated in KKMC [19]. The known decay modes are modeled with EVTGEN [20] using world averaged branching fraction values [21], and the remaining unknown decays from the charmonium states with LUNDCHARM [22]. Final-state radiation from charged final-state particles is

incorporated with PHOTOS [23].

### III. DATA ANALYSIS

The single tag (ST) sample comprises events in which only the  $D^{*-}$  meson is reconstructed via hadronic decay modes. The double tag (DT) sample consists of events in which the leptonic decays of  $D^{*+} \rightarrow \ell^+\nu_\ell$  are reconstructed in the systems recoiling against the ST candidates [24]. The branching fraction for  $D^{*+} \rightarrow \ell^+\nu_\ell$  can be determined by

$$\mathcal{B}(D^{*+} \rightarrow \ell^+\nu_\ell) = \frac{N_{\text{DT}}^{\text{tot}}}{N_{\text{ST}}^{\text{tot}} \bar{\epsilon}_{D^{*+} \rightarrow \ell^+\nu_\ell}}, \quad (2)$$

where  $N_{\text{ST}}^{\text{tot}}$  and  $N_{\text{DT}}^{\text{tot}}$  are the ST and DT yields in the data sample, respectively, and  $\bar{\epsilon}_{D^{*+} \rightarrow \ell^+\nu_\ell} = \sum_i (N_{\text{ST}}^i \epsilon_{\text{DT}}^i / f \epsilon_{\text{ST}}^i) / N_{\text{ST}}^{\text{tot}}$  is the effective averaged efficiency of reconstructing the  $D^{*+} \rightarrow \ell^+\nu_\ell$  decay weighted by the ST yields, where  $i$  indicates the  $i^{\text{th}}$  tag mode. Here,  $\epsilon_{\text{ST}}^i$  and  $\epsilon_{\text{DT}}^i$  are the efficiencies of reconstructing the ST and DT candidates in the  $i^{\text{th}}$  tag mode (called the ST efficiency and DT efficiency respectively). The ST efficiency is the average efficiency of ST  $D^{*-}$  from  $D^{*+}D^{*-}$ ,  $D^{*-}D^+$ ,  $D^0D^{*-}\pi^+$ ,  $D^+D^{*-}\pi^0$ .  $f$  represents the ratio of the number of  $D^{*-}$  contributed by all processes to that by  $D^{*+}D^{*-}$  pairs,  $f = (2\sigma_{D^{*-}D^{*+}} + \sigma_{D^{*-}D^+} + \sigma_{D^0D^{*-}\pi^+} + \sigma_{D^+D^{*-}\pi^0}) / 2\sigma_{D^{*+}D^{*-}}$ , where the  $\sigma$  denotes the corresponding cross section [25, 26]. Note that, the cross section of  $D^+D^{*-}\pi^0$  is set to be half of  $D^0D^{*-}\pi^+$ , according to the isospin symmetry.

#### A. Single-tag analysis

The ST candidates are reconstructed through the two main decay modes of  $D^{*-}$  mesons:  $\bar{D}^0\pi^-$  and  $D^-\pi^0$ . To reconstruct  $\bar{D}^0$  mesons, three hadronic decay modes,  $K^+\pi^-$ ,  $K^+\pi^-\pi^0$ , and  $K^+\pi^-\pi^+\pi^-$ , are used. To reconstruct  $D^-$  mesons, six hadronic decay modes,  $K^+\pi^-\pi^-$ ,  $K^+K^-\pi^-$ ,  $K^+\pi^-\pi^-\pi^0$ ,  $K_S^0\pi^-$ ,  $K_S^0\pi^-\pi^0$ , and  $K_S^0\pi^+\pi^-\pi^-$  are used.

All charged tracks are required to be within the polar angle ( $\theta$ ) range of  $|\cos\theta| < 0.93$ , where  $\theta$  is defined with respect to the  $z$  axis, which is the symmetry axis of the MDC. For charged tracks not originating from  $K_S^0$  decays, the distance of closest approach to the interaction point (IP) must be less than 10 cm along the  $z$  axis,  $|V_z|$ , and less than 1 cm in the transverse plane,  $|V_{xy}|$ . Particle identification (PID) for charged tracks combines measurements of the  $dE/dx$  and TOF to form likelihoods  $\mathcal{L}(h)$  ( $h = K, \pi$ ) for each hadron  $h$  hypothesis. Tracks are identified as charged kaons and pions by comparing the likelihoods for the kaon and pion hypotheses,  $\mathcal{L}(K) > \mathcal{L}(\pi)$  and  $\mathcal{L}(\pi) > \mathcal{L}(K)$ , respectively.

Each  $K_S^0$  candidate is reconstructed from two oppositely charged tracks satisfying  $|V_z| < 20$  cm. The two charged tracks are assigned the charged pion hypothesis without imposing any PID requirements. The candidates pions are constrained to originate from a common vertex and are required to have an invariant mass within  $|M_{\pi^+\pi^-} - m_{K_S^0}| < 12$  MeV/ $c^2$ , where  $m_{K_S^0}$  is the known  $K_S^0$  mass [21]. The decay length of the  $K_S^0$  candidate is required to be twice greater than its uncertainty.

Photon candidates are identified using showers in the EMC. The deposited energy of each shower must be more than 25 MeV in the barrel region ( $|\cos \theta| < 0.80$ ) and more than 50 MeV in the end-cap region ( $0.86 < |\cos \theta| < 0.92$ ). To exclude showers associated with charged tracks, the angle subtended by the EMC shower and the position of the closest charged track at the EMC must be greater than 10 degrees as measured from the IP. To suppress electronic noise and showers unrelated to the event, the difference between the EMC time and the event start time is required to be within [0, 700] ns.

The  $\pi^0$  candidates are reconstructed through  $\pi^0 \rightarrow \gamma\gamma$  decays. The diphoton invariant masses  $M_{\gamma\gamma}$  must lie within the range [0.115, 0.150] GeV/ $c^2$ . For diphoton combinations satisfying this requirement  $M_{\gamma\gamma}$  is kinematically constrained to the known  $\pi^0$  mass [21].

If there are multiple ST candidates found, the candidate with the minimal  $|\Delta E| \equiv |E_{D^{*-}} - E_{\text{beam}}|$  is selected, where  $E_{\text{beam}}$  is the beam energy and  $E_{D^{*-}}$  is the reconstructed energy of the ST candidate in the  $e^+e^-$  CM frame. Furthermore, it is possible that there are multiple combinations having exactly the same  $\Delta E$  value for the ST modes with  $\pi^-(\pi^0)$  as final states of  $\bar{D}^0(D^-)$  decays. Specifically, in the case of  $D^{*-} \rightarrow \pi^-\bar{D}^0(D^{*-} \rightarrow \pi^0D^-)$  with  $\bar{D}^0 \rightarrow X\pi^-(D^- \rightarrow X\pi^0)$ , the value of  $\Delta E$  remains unchanged even if the two  $\pi^-(\pi^0)$  is switched. In this case, the least  $|\Delta M| \equiv |M_{D^*} - m_{D^{-(0)}}|$  is used to identify the  $\pi^{-(0)}$  meson produced from  $D^{*-}$  decays ( $\pi_{D^*}^{-(0)}$ ) for further analysis. Here,  $M_{D^*}$  is the reconstructed mass of  $D^{*-}$  candidate and  $m_{D^{-(0)}}$  is the nominal mass of the  $D^{-(0)}$  meson [21].

The  $\pi_{D^*}^{-(0)}$  candidate is required to have momentum less than 100 MeV/ $c$  to suppress backgrounds. Since the CM energies are about 160-210 MeV higher than the  $D^{*+}D^{*-}$  mass threshold, the  $D^{*-}$  is boosted. MC studies show that more than 90% of signals have  $\cos \theta_{D\pi} > 0$ , where  $\theta_{D\pi}$  is the opening angle between  $D^{0(-)}$  and  $\pi_{D^*}^{-(0)}$  in the  $e^+e^-$  CM frame. Therefore, a requirement of  $\cos \theta_{D\pi} > 0$  is applied to suppress backgrounds caused by the misreconstruction of the  $\pi_{D^*}^{-(0)}$ .

The variables  $\Delta E$ , the reconstructed mass of  $\bar{D}^0(D^-)$  candidate ( $M_D$ ), and the beam-constrained mass,  $M_{\text{BC}} = \sqrt{E_{\text{beam}}^2 - |\vec{p}_{D^{*-}}|^2}$ , where  $\vec{p}_{D^{*-}}$  is the reconstructed  $D^{*-}$  momentum in the  $e^+e^-$  CM frame, are used to further suppress combinatorial backgrounds. Requirements on these variables are listed in Table II, which

correspond to  $3\sigma$  regions for the signal process. Here  $\sigma$  stands for the standard deviations for the variables that are determined by the fits on the corresponding distributions for each tag.

To determine the ST signal yield, a maximum-likelihood fit to the distributions of  $\Delta M$  is performed for each tag mode at each energy point. In the fit, the signal shape is described by a double-Gaussian function and the background shape by a third-order polynomial. The ST yields ( $N_{\text{ST}}^i$ ) and efficiencies ( $\epsilon_{\text{ST}}^i$ ) are extracted from the fits to data and inclusive MC samples, respectively. Signal regions of  $\Delta M$  are set at three times the resolution. Figure 2 shows the fit results at 4.178 GeV and Table III summarizes the signal regions of  $\Delta M$ , ST signal yields, and ST efficiencies at 4.178 GeV. The fit results at other energy points can be found at Appendix A. These fits give a total ST yield of  $N_{\text{ST}}^{\text{tot}} = 516256 \pm 1870$  at 4.178-4.226 GeV.

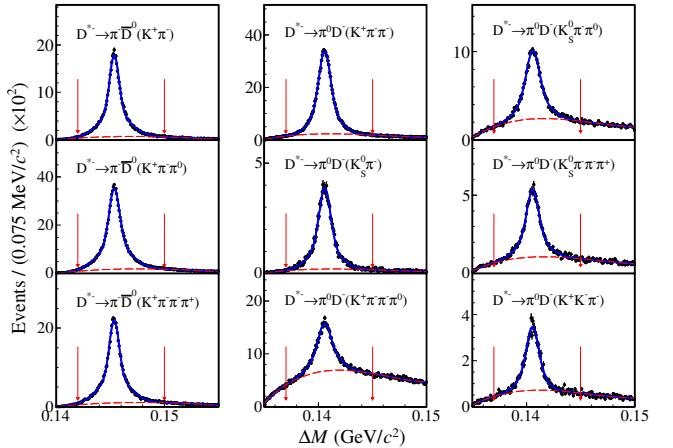

FIG. 2. Fits to the  $\Delta M$  distributions of the accepted ST  $D^{*-}$  candidates at  $\sqrt{s} = 4.178$  GeV. The points with error bars are data. The blue solid curves and red dashed curves represent the best fits and fitted combinatorial backgrounds, respectively. The pairs of red arrows indicate the  $\Delta M$  signal region.

## B. Double-tag analysis

To search for the  $D^{*+} \rightarrow \ell^+\nu_\ell$  decays recoiling against ST candidates, we require that there is only one charged track (the number of extra charged tracks,  $N_{\text{extra}}^{\text{charge}}$ , is zero), which is identified as an  $e^+$  or a  $\mu^+$ , and the maximum energy of photon(s) not used in the ST candidate selection,  $E_{\text{extra}}^{\max}\gamma$ , must be less than 0.3 GeV, to suppress backgrounds associated with photon(s).

Measurements in the MDC, TOF and EMC are used to construct combined likelihoods ( $\mathcal{L}'$ ) under the positron, pion, and kaon hypotheses. Positron candidates are required to satisfy  $\mathcal{L}'(e) > 0.001$  and  $\mathcal{L}'(e)/(\mathcal{L}'(e) + \mathcal{L}'(\pi) +$

TABLE II. ST selection requirements on  $\Delta E$ ,  $M_D$ , and  $M_{BC}$  for each tag modes.

$D^- \rightarrow K_S^0 \pi^- \pi^+ \pi^-$	(0.137, 0.145)	$10922 \pm 225$	$8.65 \pm 0.08$
Total		$326405 \pm 1567$	

$\mathcal{L}'(K) > 0.8$ . To reduce background from hadrons and muons, the positron candidate is further required to have a deposited energy in the EMC greater than 80% of its momentum as determined from its trajectory in the MDC. Muon PID uses information from the EMC and MUC. The energy deposited in the EMC is required to be in the range of (0.0, 0.3) GeV. The muon penetrates further than other charged particles, and thus has a deeper hit depth in the MUC. The penetrating depths of muon candidates are required to satisfy the criteria listed in Table IV.

Neutrinos cannot be detected directly by the BESIII detector. However, their presence can be inferred in the process  $e^+ e^- \rightarrow D^{*+} D^{*-}$  by the kinematic variable  $U_{\text{miss}} = E_{\text{miss}} - |\vec{p}_{\text{miss}}|$ , where  $E_{\text{miss}}$  is missing energy calculated by  $E_{\text{miss}} = E_{\text{cm}} - E_{D^{*+}} - E_{\ell^+}$ , and  $\vec{p}_{\text{miss}}$  is the momentum of the missing neutrino given by  $\vec{p}_{\text{miss}} = -\vec{p}_{D^{*+}} - \vec{p}_{\ell^+}$ , where  $E_{\ell^+}$  and  $\vec{p}_{\ell^+}$  are the energy and momentum of  $e^+$  or  $\mu^+$  in the  $e^+ e^-$  CM frame, respectively. A signal would manifest itself as an excess of events around  $U_{\text{miss}} = 0$ . No significant signal is seen in the events passing the  $D^{*+} \rightarrow \ell^+ \nu_\ell$  selection, as can be seen in Fig. 3.

The  $U_{\text{miss}}$  signal and sideband regions are defined based on the signal MC events. Fits to signal MC events distributions are performed by using a double Gaussian function to model the signal shape and

TABLE IV. Requirements of the hit depth in the MUC for muon candidate.

a third-order polynomial to model the background shape. The  $U_{\text{miss}}$  signal region is set to be three standard deviations around the fitted peaks, which correspond to  $(-0.055, 0.067)$  GeV for  $D^{*+} \rightarrow e^+ \nu_e$  and  $(-0.053, 0.058)$  GeV for  $D^{*+} \rightarrow \mu^+ \nu_\mu$ , respectively. The sideband region for both selections is defined to be  $U_{\text{miss}}$  within  $[-0.2, 0.2]$  GeV and lying outside the signal region.

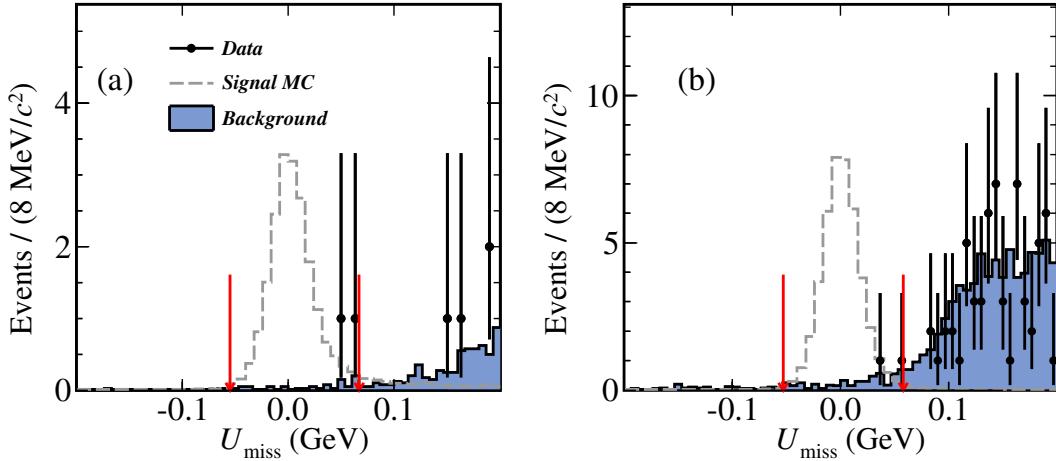

FIG. 3. The  $U_{\text{miss}}$  distributions for the (a)  $D^{*+} \rightarrow e^+ \nu_e$  and (b)  $D^{*+} \rightarrow \mu^+ \nu_\mu$  candidates. The points with error bars are data combined from all energy points. The blue filled histogram is the simulated background derived from the inclusive MC sample. The dashed histogram is the signal MC events with arbitrarily normalization for visualization. The signal region lies inside the red arrows, and the sideband region lies outside.

The DT efficiencies for  $D^{*+} \rightarrow \ell^+ \nu_\ell$  events are calculated from the number of signal MC events falling into the signal regions divided by the number of generated signal MC events, in which  $D^{*+}$  decays to the  $\ell^+ \nu_\ell$  final state and  $D^{*-}$  decays to the tag modes. The DT efficiencies ( $\epsilon_{\text{DT}}^i$ ) for each tag mode at  $\sqrt{s} = 4.178$  GeV are listed in Table V, and those for the other energy points can be found in Appendix B. From the DT efficiencies presented in this table, and the ST efficiencies listed in Table III, the effective averaged efficiencies for reconstructing the  $D^{*+} \rightarrow \ell^+ \nu_\ell$  decay,  $\bar{\epsilon}_{D^{*+} \rightarrow \ell^+ \nu_\ell}$ , are determined to be  $(80.90 \pm 1.46)\%$  for  $D^{*+} \rightarrow e^+ \nu_e$  and  $(68.86 \pm 1.23)\%$  for  $D^{*+} \rightarrow \mu^+ \nu_\mu$ , after applying the muon PID systematic correction as described in Sec. V.

TABLE V. The DT efficiencies of  $D^{*+} \rightarrow \ell^+ \nu_\ell$  at 4.178 GeV. Uncertainties are statistical only.

Tag mode	$\epsilon_{\text{DT}}^i (\%)$	
	$D^{*+} \rightarrow e^+ \nu_e$	$D^{*+} \rightarrow \mu^+ \nu_\mu$
$\bar{D}^0 \rightarrow K^+ \pi^-$	$6.90 \pm 0.06$	$6.47 \pm 0.06$
$\bar{D}^0 \rightarrow K^+ \pi^- \pi^+ \pi^-$	$3.87 \pm 0.07$	$3.72 \pm 0.07$
$\bar{D}^0 \rightarrow K^+ \pi^- \pi^0$	$4.10 \pm 0.05$	$3.91 \pm 0.04$
$D^- \rightarrow K^+ \pi^- \pi^-$	$17.38 \pm 0.09$	$16.65 \pm 0.09$
$D^- \rightarrow K^+ K^- \pi^-$	$13.31 \pm 0.11$	$12.75 \pm 0.11$
$D^- \rightarrow K^+ \pi^- \pi^- \pi^0$	$8.81 \pm 0.09$	$8.27 \pm 0.08$
$D^- \rightarrow K_S^0 \pi^-$	$16.97 \pm 0.11$	$16.08 \pm 0.11$
$D^- \rightarrow K_S^0 \pi^- \pi^0$	$9.37 \pm 0.12$	$9.01 \pm 0.12$
$D^- \rightarrow K_S^0 \pi^- \pi^+ \pi^-$	$9.88 \pm 0.16$	$9.54 \pm 0.16$

From counting, we determine  $N_{\text{SR}}^{\text{data}}$ , the number of events in the  $U_{\text{miss}}$  signal region in data, and  $N_{\text{SB}}^{\text{data}}$ , the number in the data sideband region. The corresponding numbers in the inclusive MC sample are  $N_{\text{SR}}^{\text{MC}}$  and  $N_{\text{SB}}^{\text{MC}}$ . We estimate the number of background events in the sig-

nal region to be  $N_{\text{SB}}^{\text{data}}$  scaled by the factor  $(N_{\text{SR}}^{\text{MC}}/N_{\text{SB}}^{\text{MC}})$ . The number of events in each region for data and MC simulation are listed in Table VI.

#### IV. UPPER LIMITS OF BRANCHING FRACTIONS

The upper limits on the signal yields of the  $D^{*+} \rightarrow e^+ \nu_e$  and  $D^{*+} \rightarrow \mu^+ \nu_\mu$  decays at the 90% confidence level,  $N_{\text{UL}}$ , are calculated by using a frequentist method with an unbounded profile likelihood treatment of systematic uncertainties, as implemented by the TROLKE package in the ROOT software [27], where the number of the signal and background events are assumed to follow a Poisson distribution, the detection efficiency is assumed to follow a Gaussian distribution, and the systematic uncertainty, which will be discussed below, is considered to be the standard deviation of the efficiency.

Since the effective averaged efficiency  $\bar{\epsilon}_{D^{*+} \rightarrow \ell^+ \nu_\ell}$  has been considered in the determination of  $N_{\text{UL}}$  by the TROLKE package, the upper limits of the branching fractions are given by

$$\mathcal{B}_{\text{UL}} = \frac{N_{\text{UL}}}{N_{\text{ST}}^{\text{tot}}}. \quad (3)$$

Inserting the relevant quantities from Table VI into Eq. 3, the upper limits of the branching fractions of  $D^{*+} \rightarrow e^+ \nu_e$  and  $D^{*+} \rightarrow \mu^+ \nu_\mu$  are determined to be  $1.1 \times 10^{-5}$  and  $4.1 \times 10^{-6}$ , respectively, at the 90% confidence level.

TABLE VI. Summary of the quantities used for branching fraction calculation.

Signal mode	$N_{\text{ST}}^{\text{tot}}$	$N_{\text{SR}}^{\text{data}}$	$N_{\text{SB}}^{\text{data}}$	$N_{\text{SR}}^{\text{MC}}$	$N_{\text{SB}}^{\text{MC}}$	$\bar{\epsilon}_{D^{*+} \rightarrow \ell^+ \nu_\ell} (\%)$	$N_{\text{UL}}$	$\mathcal{B}_{\text{UL}}$
$D^{*+} \rightarrow e^+ \nu_e$	$516256 \pm 1870$	2	4	34	239	$80.90 \pm 1.46$	5.9	$1.1 \times 10^{-5}$
$D^{*+} \rightarrow \mu^+ \nu_\mu$		1	61	182	2872	$68.86 \pm 1.23$	2.2	$4.3 \times 10^{-6}$

## V. SYSTEMATIC UNCERTAINTY

Table VII summarizes the assigned systematic uncertainties, which are discussed below.

The systematic uncertainties associated with  $e^\pm(\mu^\pm)$  tracking and PID efficiencies are studied with a control sample of  $e^+e^- \rightarrow \gamma e^+e^-(\mu^+\mu^-)$  events. The efficiencies determined from this control sample are used to correct the efficiencies measured in the signal MC samples in the two dimensions of momentum and  $\cos\theta$  and the difference in result taken as the corresponding systematic uncertainty for the tracking and electron PID efficiency. In the case of the muon PID, the systematic uncertainty is assigned by propagating the statistical uncertainty associated with the control sample to the branching-fraction measurement .

The uncertainty in the total number of ST  $D_s^-$  mesons is assigned to be 2.9% by examining the changes in the fit yields when varying the signal and background shapes in the fit. The nominal signal shape is replaced with an MC-simulated shape convolved with a double-Gaussian function and the nominal background shape with an ARGUS function [28].

The uncertainties associated with the extra photon energy and extra charged track requirements are studied with samples of the light hadronic processes  $e^+e^- \rightarrow K^+K^-\pi^+\pi^-$ ,  $\pi^+\pi^-\pi^+\pi^-$ ,  $K^+K^-\pi^+\pi^-\pi^0$  and  $\pi^+\pi^-\pi^+\pi^-\pi^0$ . The ratios of the average efficiencies of data to those of simulation are found to be  $1.008 \pm 0.001$  for the extra photon-energy requirement and  $0.998 \pm 0.001$  for the extra charged-track requirement. We assign 0.8% and 0.2% as the systematic uncertainties from the extra photon energy and charged track requirements, respectively.

The uncertainty associated with the ST efficiency does not fully cancel. Because the ST efficiencies estimated with the inclusive and signal MC samples differ from each other due to different multiplicities, there can be a bias associated with the reconstruction of the tag mode. We study the variation in tracking/PID efficiencies for different multiplicities, and take the combined differences between data and MC simulation, 0.7% for  $D^{*+} \rightarrow e^+ \nu_e$  and 0.8%  $D^{*+} \rightarrow \mu^+ \nu_\mu$ , as the corresponding tag-bias uncertainties. The efficiency for reconstructing the tag modes almost cancel with the DT method, and the residual effects are referred to as tag bias.

The systematic uncertainty caused by the change of  $f$  factor is estimated to be 4.1% as a result of cross section uncertainty of  $D^{*+}D^{*-}$ ,  $D^{*-}D^+$ ,  $D^0D^{*-}\pi^+$ ,  $D^+D^{*-}\pi^0$ ,

even including  $D^{*0}D^{*-}\pi^+$  [29] and  $D^{*+}D^{*-}\pi^0$ . Similarity, according to the isospin symmetry, the cross section of  $D^{*+}D^{*-}\pi^0$  is set to be half of  $D^{*0}D^{*-}\pi^+$ . The uncertainty in the knowledge of the ST and DT efficiencies arising from the limited MC sample sizes, as shown in Table III and V, is evaluated to be 1.0% for each signal decay mode.

TABLE VII. Relative systematic uncertainties (in %) from each source.

Source	$D^{*+} \rightarrow e^+ \nu_e$	$D^{*+} \rightarrow \mu^+ \nu_\mu$
Tracking	0.2	0.2
PID	0.5	0.5
$N_{\text{ST}}^{\text{tot}}$	2.9	2.9
$E_{\text{extra } \gamma}^{\text{max}} < 0.3 \text{ GeV}$	0.8	0.8
$N_{\text{extra}}^{\text{charge}} = 0$	0.2	0.2
Tag bias	0.7	0.8
$f$ factor	4.1	4.1
MC sample sizes	1.0	1.0
Total	5.3	5.3

## VI. CONCLUSION

Using a data sample corresponding to an integrated luminosity of  $6.32 \text{ fb}^{-1}$ , taken at  $\sqrt{s} = 4.178\text{-}4.226 \text{ GeV}$  by the BESIII detector, we search for the leptonic decays of  $D^{*+} \rightarrow e^+ \nu_e$  and  $D^{*+} \rightarrow \mu^+ \nu_\mu$  for the first time. No significant signal is observed. We set upper limits on the branching fractions of these decays, which are  $\mathcal{B}(D^{*+} \rightarrow e^+ \nu_e) < 1.1 \times 10^{-5}$  and  $\mathcal{B}(D^{*+} \rightarrow \mu^+ \nu_\mu) < 4.3 \times 10^{-6}$  at the 90% confidence level. The larger data sets that are foreseen to be collected at BESIII in the coming years [12] will offer the opportunity to further improve the sensitivity to these decays.

## ACKNOWLEDGMENTS

The BESIII collaboration thanks the staff of BEPCII and the IHEP computing center for their strong support. ## Appendix A: ST yields and efficiencies

Tables VIII and IX summarize the ST efficiencies and the ST yields in data at  $\sqrt{s} = 4.189 - 4.226$  GeV, respectively. Figures 4–8 show the fits to the  $\Delta M$  distributions of the accepted ST  $D^{*-}$  candidates at these energy points.

## Appendix B: DT efficiencies

Tables X and XI summarize the DT efficiencies of  $D^{*+} \rightarrow e^+ \nu_e$  and  $D^{*+} \rightarrow \mu^+ \nu_\mu$  at  $\sqrt{s} = 4.189 - 4.226$  GeV, respectively.

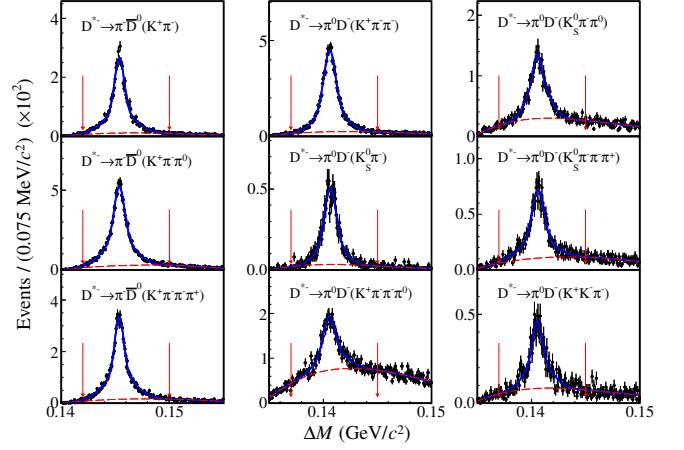

FIG. 4. Fits to the  $\Delta M$  distributions of the accepted ST  $D^{*-}$  candidates at  $\sqrt{s} = 4.189$  GeV. The points with error bars are data. The blue solid curves and red dashed curves represent the best fits and fitted combinatorial backgrounds, respectively. The pairs of red arrows indicate the  $\Delta M$  signal region.

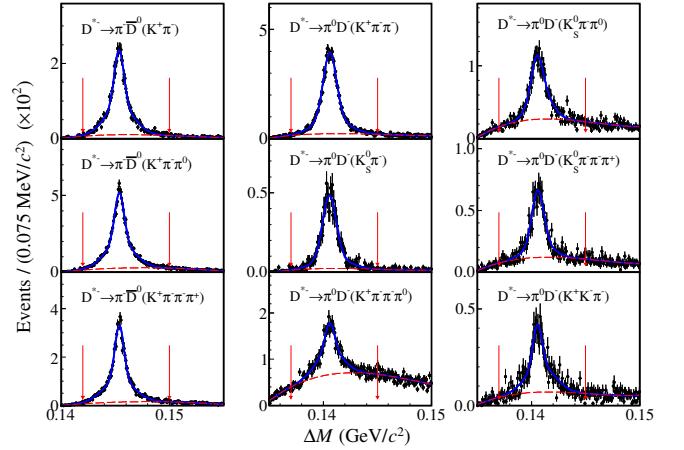

FIG. 5. Fits to the  $\Delta M$  distributions of the accepted ST  $D^{*-}$  candidates at  $\sqrt{s} = 4.199$  GeV. The points with error bars are data. The blue solid curves and red dashed curves represent the best fits and fitted combinatorial backgrounds, respectively. The pairs of red arrows indicate the  $\Delta M$  signal region.

The blue solid curves and red dashed curves represent the best fits and fitted combinatorial backgrounds, respectively. The pairs of red arrows indicate the  $\Delta M$  signal region.

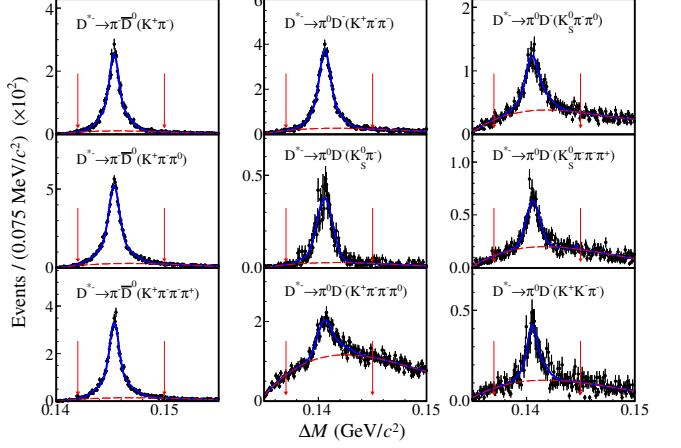

FIG. 8. Fits to the  $\Delta M$  distributions of the accepted ST  $D^{*-}$  candidates at  $\sqrt{s} = 4.226$  GeV. The points with error bars are data. The blue solid curves and red dashed curves represent the best fits and fitted combinatorial backgrounds, respectively. The pairs of red arrows indicate the  $\Delta M$  signal region.

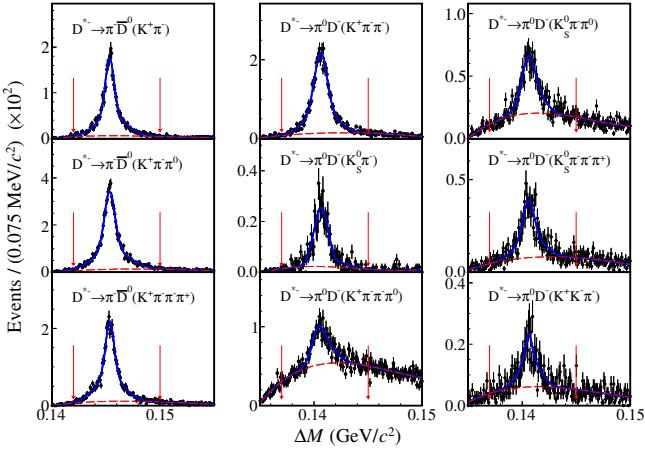

FIG. 7. Fits to the  $\Delta M$  distributions of the accepted ST  $D^{*-}$  candidates at  $\sqrt{s} = 4.219$  GeV. The points with error bars are data. The blue solid curves and red dashed curves represent the best fits and fitted combinatorial backgrounds, respectively. The pairs of red arrows indicate the  $\Delta M$  signal region.
