#### Abstract

For large language models (LLMs) like NLLB and GPT, translating idioms remains a challenge. Our goal is to enhance translation fidelity by improving LLM processing of idiomatic language while preserving the original linguistic style. This has a significant social impact, as it preserves cultural nuances and ensures translated texts retain their intent and emotional resonance, fostering better cross-cultural communication. Previous work has utilized knowledge bases like IdiomKB by providing the LLM with the meaning of an idiom to use in translation. Although this method yielded better results than a direct translation, it is still limited in its ability to preserve idiomatic writing style across languages. In this research, we expand upon the knowledge base to find corresponding idioms in the target language. Our research performs translations using two methods: The first method employs the SentenceTransformers model to semantically generate cosine similarity scores between the meanings of the original and target language idioms, selecting the best idiom (Cosine Similarity method). The second method uses an LLM to find a corresponding idiom in the target language for use in the translation (LLM-generated idiom method). As a baseline, we performed a direct translation without providing additional information. Human evaluations on the English -> Chinese, and Chinese -> English show the Cosine Similarity Lookup method outperformed others in all GPT4o translations. To further build upon IdiomKB, we developed a low-resource Urdu dataset containing Urdu idioms and their translations. Despite dataset limitations, the Cosine Similarity Lookup method shows promise, potentially overcoming language barriers and enabling the exploration of diverse literary works in Chinese and Urdu. For access to the code and replication of our experiments, please visit this GitHub.(https://github.com/mzx05/IdiomaticTranslationResearch)

## 1 Introduction

The primary challenge faced is enabling large language models (LLMs) to capture the cultural and emotional essence of the original author's words-frequently lost in direct translations (Levin et al., 2014). Idioms particularly highlight this difficulty; they differ significantly across languages and are deeply embedded in cultural contexts, requiring additional cultural knowledge for accurate translation (Fadaee et al., 2018). Previous work has made efforts to enhance LLMs like NLLB and GPT for idiomatic translation and has primarily relied on augmenting these models with knowledge bases such as IdiomKB (Li et al., 2023). These knowledge bases provide meanings to assist in translating idioms. However, current methods still face challenges in preserving the idiomatic style and cultural nuances of the original text (Levin et al., 2014). Despite advancements, existing methods often struggle to maintain the idiomatic writing style in translated texts. The difficulty lies in accurately capturing the cultural and emotional essence embedded in idiomatic expressions, which are highly context-dependent and vary across languages (Shao et al., 2017). This research addresses these challenges by expanding upon existing knowledge bases to include idiomatic expressions from both source and target languages. Specifically, we introduce a novel method termed Cosine Similarity Lookup that utilizes a refined dataset of the chosen language of translation with corresponding idioms that are inserted according to the direct translation from the previous language. This is optimized for SentenceTransformer embeddings (Li et al., 2023). We introduced and benchmarked methods to ensure fidelity in translating idiomatic sentences across languages, validated through human evaluation metrics, alongside compiling a benchmark dataset of Urdu idioms indexed by their English meanings.

## 2 Related Works

### 2.1 Limitations in Translation Technology

From a literary standpoint, idioms are figurative, institutionalized expressions that enrich speech and writing, demonstrating mastery of a language. Language models must understand and interpret idioms, especially when translating from one language to another. Recent work has used IdiomKB as a knowledge base for translating idioms, achieving some success with language models $(\mathrm{Li}$, Shuang, et al. "Translate Meanings, Not Just Words: IdiomKB's Role in Optimizing Idiomatic Translation with Language Models." ArXiv abs/2308.13961 (2023): n. pag.). This knowledge base pairs idioms in a language with their meanings in English, Chinese, and Japanese. In their method, they use this to provide the translation model with the figurative meaning of the idiom in the sentence. However, this technique fell short of consistently super accurate results. The knowledge base is also relatively small, limited to only three languages, and it does not include any low-resource languages. Building on these techniques for idiomatic translation is the use of retrieval-augmented models (KNN-MT) and the upweighting of training loss on potentially idiomatic sentences (Liu, Emmy, et al. "Crossing the Threshold: Idiomatic Machine Translation through Retrieval Augmentation and Loss Weighting." Conference on Empirical Methods in Natural Language Processing (2023)). This showed improvements in translations for idiomatic sentences along with slight improvements in non-idiomatic sentences as well. However, limitations include the use of synthetic data, limited languages, and the heavy reliance on high-quality training data. Past research has focused on translating an idiom in the original language to the figurative meaning in the target language. Although this may convey the message, it fails to be a true translation because the idiomatic sentence style is lost.

### 2.2 Next Steps to Build On IdiomKB

As evidenced by Li and Chen, the use of specialized knowledge bases such as IdiomKB has proven beneficial. However, the limited scope of these resources, covering only a few languages, constrains their utility in broader linguistic contexts (Li, Shuang, et al. "Translate Meanings, Not Just Words: IdiomKB's Role in Optimizing Idiomatic Translation with Language Models." ArXiv abs/2308.13961 (2023): n. pag.). This highlights the need to expand these databases to encompass a wider array of languages and idiomatic expressions. We also hope to build on the use of a knowledge base in idiomatic translation by using it to translate an idiom in one language to an idiom in another language. This would better capture cultural nuances and help maintain the style of the idiomatic sentence across languages.. The inherent complexity of idioms is underscored by research from Dankers and Lucas, who analyze the compositional challenges faced by Transformer models in handling
idiomatic expressions. Their findings reveal that while these models adeptly process standard grammatical constructions, they frequently misinterpret the non-compositional nature of idioms, leading to incomplete or incorrect translations ("Can Transformers be Too Compositional? Analyzing Flexibility in Multi-Word Expression Translation," Semantic Scholar (2023)). This suggests that current models need enhancements in semantic flexibility to better accommodate the abnormalities of idiomatic language. Further highlighting the translation challenges, Shao and Sennrich's evaluation of machine translation performance on idiomatic texts points out that even advanced models struggle to maintain the expressive depth and cultural nuances of idioms, often resulting in translations that are either too literal or misleading ("Evaluating Machine Translation Performance on Text with Idiomatic Expressions," Semantic Scholar (2023)). The necessity for more refined training datasets specifically tailored to improve the handling of idiomatic expressions within translation systems becomes an emphasized need after understanding the limitations of such technology.

### 2.3 Newer Idiom Knowledge Resources

In response to these challenges, new resources such as the EPIE dataset introduced by Saxena and Paul are emerging. This dataset aims to enhance the identification and translation of idiomatic expressions by providing context-rich examples of their usage across various languages ("EPIE Dataset: A Corpus For Possible Idiomatic Expression Identification," Semantic Scholar (2023)). Such resources are invaluable for developing more sophisticated models capable of recognizing and translating idioms accurately. The work of Liu et al. offers a promising direction through the application of retrieval-augmented models and idiomatic sentence-focused training techniques. Their approach shows improvements in translating idiomatic sentences and enhances the overall fluency of translated texts, suggesting a viable pathway to overcome some inherent limitations of current translation models ("Crossing the Threshold: Idiomatic Machine Translation through Retrieval Augmentation and Loss Weighting," Semantic Scholar (2023)).

## 3 Method

### 3.1 Dataset construction

For the English-to-Chinese translation, we used the "MWE-PIE" (Zhjjn, 2021) dataset that had 1,197 English idioms with around 5 sentences per idiom for a total of 5,170 sentences. For the Chinese-to-English translation, we used the CCT "cheng yu" dataset (Jiang et al., 2018) which had 108,987 Chinese sentences that contained 7,397 unique idioms. For future use with the cosine similarity method, we re-formatted the datasets so the English meaning was the key with the meanings and idioms from other languages as the values. We are indexing on the English meanings so that semantically comparing the English meanings of idioms is made easier(Li et al., 2023). For the Urdu dataset construction, we found a dataset with 2,111 Urdu idioms(with repeats) (ul Hassan, 2024) and their English meanings/idioms. We then found matching English idioms when they existed from our English idiom dataset and, using GPT4o, generated English sentences for those that we did not already have sentences that we flagged.

### 3.2 Translating idioms

We tested three translation methods: (1) Cosine similarity lookup, (2) LLM-Generated Idioms, and (3) Direct Translation. For the EN -> ZH and ZH $->$ EN we evaluated a random subset of 500 sentences and for the EN -> UR we evaluated on 216 sentences. The Urdu idiom dataset was limited because we only translated the idiomatic sentences that had corresponding English and Urdu idioms. All methods were translated with GPT-3.5-Turbo and GPT-4o. For all translations, we set the temperature to 0.7 .

Figure 1: Dataset Construction and Idiom Translation Method Diagram with Cosine Similarity

Cosine Similarity Lookup Method In the Cosine similarity lookup method, we extracted idioms from sentences and searched for their meanings in the data. Using SentenceTransformers paraphrase-MiniLM-L6-v2, we generated embeddings for English meanings and compared them with target language idioms using cosine similarity with a threshold of 0.7 to find the best match. If no match was found, we used the English meaning for translation. For the idioms that did find a match, we prompted GPT4o to choose/confirm an idiom if the lookup method found corresponding idioms in the dataset. We then translate the sentence while providing the matching target language idiom.

| Cosine Similarity Lookup Prompt 1 | You are a linguistic researcher on idioms and are good at Chinese and English. Choose the best Chinese idiom that matches the following English idiom and its definition. English idiom: '[English idiom]' English definition: '[English definition]' Here are some options: '[Chinese idioms]' |
| :---: | :---: |
| $\underset{\text { Prompt } 2}{\text { Cosine Similarity Lookup }}$ | '[Chinese idiom 1]' (0.78), '[Chinese idiom 2]' (0.72), '[Chinese idiom 3]' (0.70), '[Chinese idiom 4]' (0.72) Please select the most relevant Chinese idiom and provide a brief explanation. |
| Cosine Similarity Lookup Prompt 3 | '[English idiom]' means '[Chinese idiom]'. Given the above knowledge, translate this sentence to Chinese: '[English sentence]'. |

LLM-Generated Idioms Method For the LLM-Generated Idioms method we first use GPT 4o to generate corresponding idioms in the target language that match the idiom in the original language. We give an option for the model to find up to 3 matches, specifically clarifying that it is acceptable to not find any match at all to minimize hallucinations. Then we prompt the model again to choose the best match from the top 3. We do this in order to stay consistent with the GPT confirmation performed in the Cosine Similarity Lookup method. Lastly, we prompt the model to use the top LLM-generated idiom when translating the sentence.

| LLM Generated Self-CoT Prompt 1 | You are a linguistic researcher on idioms and good at Chinese and English. You'll be provided an English idiom and your task is to: 1. First provide the definition of the idiom: '[Placeholder for English idiom]'. 2. Then find the three most similar Chinese idioms to the English idiom: '[English idiom]', and make sure to maintain context and cultural nuances. |
| :---: | :---: |
| LLM Generated Self-CoT Prompt 2 | Follow these instructions: 1. It is okay if you cannot find three most similar Chinese idioms, return as many as you can find. 2. It is okay if there is NO Chinese idiom that has the same meaning, in which case ONLY define the English idiom without any extra words. 3. For the idioms that you do find a good match, ONLY respond with the Chinese idiom without pinyin and it should be an actual Chinese idiom not just the literal translation to Chinese. |
| LLM Generated Self-CoT Prompt 3 | You are a linguistic researcher on idioms and are good at Chinese and English. Choose the best Chinese idiom that matches the following English idiom and its definition. English idiom: '[English idiom]' English definition: '[English definition]' Here are some options: Chinese idiom 1: '[Chinese idiom 1]' Chinese idiom 2: '[Chinese idiom 2]' Chinese idiom 3: '[Chinese idiom 3]' Please select the most relevant Chinese idiom and provide a brief explanation. |
| LLM Generated Self-CoT Prompt 4 | You are a linguistic researcher on idioms and are good at Chinese and English. '[English idiom]' means '[Chinese idiom]'. Given the above knowledge, translate the following sentence to Chinese: '[English sentence]' |

Direct Translation Method The direct translation method simply prompts the model to translate the sentence without providing additional information about the idiom. This method is the baseline that we compare the performance of the other two methods.

$$
\begin{array}{|l|l|}
\hline \text { Direct Translation Prompt } & \text { Translate this sentence to Chinese: '[English sentence]' } \\
\hline
\end{array}
$$

### 3.3 Evaluation method

To evaluate the translations, we compared the original sentence and the translated sentence. We used both GPT4 and GPT4o as well as human evaluations. The focus of the evaluation depended on whether the model was instructed to use a specific idiom in the translation. If there was an idiom in the translated sentence we instructed the model to focus on the idiom counterpart, but if there was not an idiom in the translated sentence we instructed the model to focus if the figurative meaning of the idiom was maintained. We did this to ensure that the evaluation prompt was fairly tailored for each translation. We also set the temperature to 0.1 for the evaluations so there is less randomness. Every translation received a score from 1-3 based on the scale outlined in the table below:

Task Prompt（No idiom）：Evaluate the idiom translation in the given Chinese transla－ tion of an English sentence．Focus on the idiom＇s figurative meaning．
Task Prompt（With idiom）：Evaluate the idiom translation in the given Chinese translation of an English sentence．Focus on the idiom＇s counterpart in the translated language．

## Evaluation Criteria：

1 point：Ignores，mistranslates，or only translates the literal meaning of the idiom． 2 points：Conveys basic figurative meaning but may lack refinement or have minor imperfections． 3 points：Exceptional translation，accurately conveying figurative meaning，context，and cultural nuances．
Test Data：Evaluate the following translation：English sentence：＜source＞Idiom in the English sentence：＜idiom＞Chinese translation：＜translation＞Evaluation（score only）：＜score＞

## 4 Results

The evaluations presented below reveal the performance of different models for translating idiomatic expressions from English to Chinese and from Chinese to English．The GPT－4o translations，expec－ tantly，outperformed the GPT3．5－Turbo translations．Regarding the translation model，the GPT－4o evaluations consistently score the translations lower than the GPT4 evaluations（Figure 2，Page 8）； the evaluation done by GPT－4o matched more closely with the human evaluations．Using a binary correlation we found that the GPT4o score matched the human evaluation score $65 \%$ of the time while the GPT4 score only matched $53 \%$ of the time．The superior GPT4o model was more critical of the idiom translations than GPT4 making it a more human－like evaluation．Although the LLM evaluations typically did not score the Cosine Similarity Lookup method the highest，the GPT－4o Cosine Similarity Lookup method scored the highest on the human evaluations（ which were evaluated using the same criteria as the LLM），making it a promising and viable method．For the EN－＞ZH translation， 238 idioms did not find a match，and 262 did．For ZH－＞EN， 386 idioms did not find a match and 114 did．Despite the dataset not being designed for idiom－to－idiom correlation，the method still found success in translation．The translations that did not find an idiom scored better than the translations that did find an idiom in the LLM evaluations．However，the human evaluations show that the translations that did find an idiom were mostly better translations．This suggests that the LLM is not adequately equipped to assess the accuracy of translations that contain idioms as it prefers the usage of the figurative meaning in the translation over a corresponding idiom．This is likely why the LLM evaluations also favored direct translation as it was better able to assess the accuracy of an idiom $->$ meaning translation rather than an idiom $->$ idiom translation．Occasionally the cosine similarity fell short when the meanings were semantically similar but not the same．For example， ＂having extremely poor or no vision＂（＂blind as a bat＂）was paired with＂having small and narrow vision；lacking in foresight（＂目光如豆＂）．These two idioms being considered semantically similar is reasonable but the differences in the meaning account for the poor idiomatic translation．The majority of Cosine Similarity Look－ups are successful such as pairing＂to remain silent or keep a secret＂（＂zip one’s lips＂）with＂keep one’s lips sealed，remain silent＂（＂缄口不言＂）．The LLM－Generated Idiom method scored lower likely due to the model not producing good idiom translations in the first place compared to the Cosine Similarity Look－up method．The outputted idioms were very sensitive to the prompt as slight variations in the prompt led to varying idioms which could be a reason for the method＇s worse performance．The direct translation performed surprisingly well because for simple idioms such as＂quality time＂it was able to successfully translate it without additional information． For the EN $->$ UR sentences， 48 sentences were found in the English sentences dataset while 168 were generated by GPT4o．The low resource language results showed the Cosine Similarity Lookup underperforming．We attribute this to the LLM evaluations previously favoring the usage of the figurative meaning in the translation rather than a corresponding idiom，which is especially true here because，for the Urdu idioms dataset，we had a 1：1 correspondence for idioms．Following the trend of the previous translations we hypothesize that human evaluations would show positive results for the Cosine Similarity Lookup method．
4.1 Cosine similarity look-up results

Table 1: Cosine similarity look-up evaluations(En->Zh)

| Translation <br> Model | Evaluation <br> Model | Cosine Evaluations | Non-Cosine <br> Evaluations |
| :---: | :---: | :---: | :---: |
| GPT 3.5 | GPT 4.0 | 2.6527 | 2.8109 |
| GPT 3.5 | GPT-4o | 2.3092 | 2.3193 |
| GPT-4o | GPT 4.0 | 2.7290 | 2.9286 |
| GPT-4o | GPT-4o | 2.3779 | 2.5588 |

The column labeled cosine means an idiom was found during the look-up, and non-cosine means there was not an idiom found.

Table 2:Cosine similarity look-up evaluations(Zh->En)

| Translation <br> Model | Evaluation <br> Model | Cosine Evaluations | Non-cosine <br> Evaluations |
| :---: | :---: | :---: | :---: |
| GPT 3.5 | GPT 4.0 | 2.4561 | 2.7798 |
| GPT 3.5 | GPT-4o | 1.7719 | 1.8964 |
| GPT-4o | GPT 4.0 | 2.5439 | 2.8938 |
| GPT-4o | GPT-4o | 2.0526 | 2.2668 |

### 4.2 LLM-generated idioms evaluations

Table 3: LLM-generated idioms evaluations(En->Zh)

| Translation <br> Model | Evaluation <br> Model | Idiom:No <br> Idiom Ratio | No Idiom <br> Evaluations | Idiom <br> Evaluations | Total <br> Average <br> Score |
| :---: | :---: | :---: | :---: | :---: | :---: |
| GPT 3.5 | GPT 4.0 | $486: 14$ | 2.8571 | 2.7840 | 2.786 |
| GPT 3.5 | GPT-4o | $486: 14$ | 2.4286 | 2.3786 | 2.380 |
| GPT-4o | GPT 4.0 | $486: 14$ | 2.8571 | 2.7901 | 2.792 |
| GPT-4o | GPT-4o | $486: 14$ | 2.6429 | 2.4403 | 2.446 |

Table 4: LLM-generated idioms evaluations(Zh->En)

| Translation <br> Model | Evaluation <br> Model | Idiom:No <br> Idiom Ratio | No Idiom <br> Evaluations | Idiom <br> Evaluations | Total <br> Average <br> Score |
| :---: | :---: | :---: | :---: | :---: | :---: |
| GPT 3.5 | GPT 4.0 | $494: 6$ | 2.8333 | 2.6356 | 2.638 |
| GPT 3.5 | GPT-4o | $494: 6$ | 2.0000 | 1.9291 | 1.930 |
| GPT-4o | GPT 4.0 | $494: 6$ | 2.8333 | 2.8036 | 2.804 |
| GPT-4o | GPT-4o | $494: 6$ | 2.3333 | 2.3016 | 2.302 |

### 4.3 Direct translation evaluations

Table 5:Direct translation evaluations(En->Zh)

| Translation Model | Evaluation Model | Average Score |
| :---: | :---: | :---: |
| GPT 3.5 | GPT 4.0 | 2.776 |
| GPT 3.5 | GPT-4o | 2.322 |
| GPT-4o | GPT 4.0 | 2.898 |
| GPT-4o | GPT-4o | 2.638 |

Table 6:Direct translation evaluations(Zh->En)

| Translation Model | Evaluation Model | Average Score |
| :---: | :---: | :---: |
| GPT 3.5 | GPT 4.0 | 2.754 |
| GPT 3.5 | GPT-4o | 2.014 |
| GPT-4o | GPT 4.0 | 2.922 |
| GPT-4o | GPT-4o | 2.452 |

Table 7: Human evaluations

| Translation Direction and <br> Model | Method Used | Average Score |
| :---: | :---: | :---: |
| EN $\rightarrow$ ZH GPT3.5 | Cosine Similarity Lookup | 2.147 |
| EN $\rightarrow$ ZH GPT3.5 | LLM Generated | 2.180 |
| EN $\rightarrow$ ZH GPT3.5 | Direct Translation | 2.245 |
| ZH $\rightarrow$ EN GPT3.5 | Cosine Similarity Lookup | 2.428 |
| ZH $\rightarrow$ EN GPT3.5 | LLM Generated | 2.142 |
| ZH $\rightarrow$ EN GPT3.5 | Direct Translation | 2.523 |
| EN $\rightarrow$ ZH GPT4o | Cosine Similarity Lookup | 2.409 |
| EN $\rightarrow$ ZH GPT4o | LLM Generated | 2.180 |
| EN $\rightarrow$ ZH GPT4o | Direct Translation | 2.360 |
| ZH $\rightarrow$ EN GPT4o | Cosine Similarity Lookup | 2.761 |
| ZH $\rightarrow$ EN GPT4o | LLM Generated | 2.333 |
| ZH $\rightarrow$ EN GPT4o | Direct Translation | 2.619 |

The human evaluator was a part-time Mandarin teacher, who evaluated the idioms using the same evaluation prompt as the LLMs. She received the sentences for evaluations anonymously and wasn't aware of which method was used to create each sentence.

Table 8: Low resource language evaluations(En->Ur)

| Translation Model | Evaluation Model | Average Score |
| :---: | :---: | :---: |
|  | Reverse Lookup |  |
| GPT 3.5 | GPT 4.0 | 2.425 |
| GPT 3.5 | GPT-4o | 2.000 |
| GPT-4o | GPT 4.0 | 2.430 |
| GPT-4o | GPT-4o | 2.203 |
| Direct Translation |  |  |
| GPT 3.5 | GPT 4.0 |  |
| GPT-4o | GPT 4.0 | 2.481 |
| GPT 3.5 | GPT-4o | 2.879 |

Figure 2: ZH->EN Evaluations using GPT-4o for translation

## 5 Limitations

Although the results of the Cosine Similarity look-up method have been promising thus far, there have been limitations in our work that prevented the method from being an even bigger success.
Finite amount of idioms As stated earlier in the LLM-generated idioms method, we could generate a corresponding idiom in the target language for nearly every original idiom. This yielded a much higher percentage of idioms that found a match, even if they were not all perfect matches. However, the IdiomKB datasets, which were used in the Cosine Similarity look-up method, were composed of English and Chinese idioms without a 1:1 correspondence. There were 8,643 Chinese idioms and 3,990 English idioms. As a result, only about $1 / 2$ of the idioms had a match in the Cosine Similarity look-up method. Had there been a comprehensive dataset that had both the English idiom and its corresponding Chinese idiom, the method would've been much more effective, which we leave to future work. Further, we leave the expansion of the knowledge base to more low-resource languages for future work.

Inferior GPT evaluation GPT evaluation does not strongly mimic human evaluation, especially for Urdu translation, where we lacked access to an Urdu human evaluator.

## 6 Conclusion

In this paper, we presented advancements in translating idiomatic expressions using LLMs. We evaluated two methods, Cosine Similarity Look-up, and LLM-generated idioms, using Direct Translation as a baseline. Our findings indicate that the Cosine Similarity Look-up method is particularly effective in preserving idiomatic integrity and achieving higher translation fidelity. Despite sometimes yielding worse results than other methods, the Cosine Similarity Look-up method proved to be an effective and viable option. LLM-generated idioms performed well but fell short compared to the Cosine Similarity Look-up, while Direct Translation often missed idiomatic nuances. Human evaluations confirmed the effectiveness of the Cosine Similarity Look-up method, emphasizing the need for context-aware translations. The impact of this technology can be proven significant when used to enhance communication through more accurate and culturally resonant translations of literary and educational materials. By making literary works more accessible, this research can help bridge cultural gaps and promote cross-cultural literacy and education globally. It profoundly impacts literary and educational communities by preserving the original tone and style of literary works, allowing readers worldwide to experience texts as intended. By enhancing LLMs to maintain the style and tone of messages across languages, we acknowledge the crucial role idioms play in communication and how they can express authors' intent in their work, something that is often lost with direct translation from two languages.

## 7 Acknowledgments

We would like to express our gratitude to Shuang Li, Jiangjie Chen*, Siyu Yuan, Xinyi Wu, Hao Yang, Shimin Tao, and Yanghua Xiao for providing us with access to IdiomKB, which was instrumental to our research. Special thanks are also due to our research mentors, Kevin Zhu and Sean O'Brien, at the Algoverse AI Research Program for their invaluable guidance and support throughout this project. Additionally, we would like to acknowledge the invaluable assistance of Li Ping Wu, a Mandarin Teacher who participated in the human evaluations for the Mandarin idiom sets.
