Tuning Vision-Language Models with Candidate Labels by Prompt Alignment

Zhifang Zhang¹ and Beibei $Li^{1(\boxtimes)}$

College of Computer Science, Chongqing University, Chongqing, China lncs@springer.com

Abstract. Vision-language models (VLMs) can learn high-quality representations from a large-scale training dataset of image-text pairs. Prompt learning is a popular approach to fine-tuning VLM to adapt them to downstream tasks. Despite the satisfying performance, a major limitation of prompt learning is the demand for labelled data. In real-world scenarios, we may only obtain candidate labels (where the true label is included) instead of the true labels due to data privacy or sensitivity issues. In this paper, we provide the first study on prompt learning with candidate labels for VLMs. We empirically demonstrate that prompt learning is more advantageous than other fine-tuning methods, for handling candidate labels. Nonetheless, its performance drops when the label ambiguity increases. In order to improve its robustness, we propose a simple yet effective framework that better leverages the prior knowledge of VLMs to guide the learning process with candidate labels. Specifically, our framework disambiguates candidate labels by aligning the model output with the mixed class posterior jointly predicted by both the learnable and the handcrafted prompt. Besides, our framework can be equipped with various off-the-shelf training objectives for learning with candidate labels to further improve their performance. Extensive experiments demonstrate the effectiveness of our proposed framework.

Keywords: Vision-Language Models \cdot Prompt Learning \cdot Candidate Labels

1 Introduction

Large-scale vision-language models (VLMs) such as CLIP [38], ALIGN [19], and Coca [51] have become excellent base models in multiple domains, most of which employ a dual-encoder architecture to align the natural images with descriptive texts. Remarkably, this special training manner has endowed VLMs with superior zero-shot transfer performance on visual recognition tasks. In specific, during the inference, the pre-trained text encoder receives inputs in the form of mancrafted prompts, e.g., "a photo of $\langle CLS \rangle$.". Subsequently, all the generated textual embeddings are matched with the visual embedding obtained from the image encoder to predict the image category. However, the powerful zero-shot ability of VLMs was shown to be heavily dependent on the choice of handcrafted

prompts, which needs substantial efforts and professional domain knowledge to design [57]. To avoid the manual design of the prompts, *prompt learning* [57] is proposed, which treats the textual prompt as additional learnable parameters and tunes them while keeping all the parameters of the pre-trained model fixed. Later, the concept of the prompt is extended to visual prompt [20] and multi-modal prompt [22] in VLMs. Overall, there has been increasing attention paid to prompt learning due to its potential to perform significantly better than zero-shot transfer with a few sets of labelled data.

Fig. 1. There are possible candidate labels corresponding to the picture of a falcon. In the right portion of the figure, candidate labels are coloured in blue. In the candidate label set, the hidden true label is underlined to be distinct from the false-positive labels.

While prompt learning has demonstrated effectiveness and efficiency in fewshot supervised learning, the true labels must be provided for the training data used in prompt learning. This is a significant defect and will limit the usage of prompt learning in various real-world scenarios because we may be unable to collect accurate labels due to security issues or labelling difficulties. Fortunately, obtaining a set of candidate labels that includes the true label in these situations is easier. For example, as shown in Figure 1, it is challenging to determine which is the true label from 'Hawk', 'Eagle', and 'Falcon', hence all these three labels can be considered as candidate labels during the annotation process of this bird recognition task. As we see, learning with only candidate labels (also widely known as *partial-label learning* [44,47,30,11]) is practically significant, which also has arisen in many vital applications such as web mining [28], online annotation [41] and ecoinformatics [27]. Nevertheless, existing PLL methods primarily focus on training a model from scratch, and the effectiveness of PLL in the new training paradigm called prompt learning remains unconfirmed. To bridge this research gap, we, for the first time, explore the validity and potential approaches for prompt learning with candidate labels.

This paper provides empirical evidence that prompt learning combined with the prevailing PLL training objectives exhibits superior performance when learning with only candidate labels. Moreover, we conjecture the reason behind the robustness of prompt learning to candidate labels lies in its special position of learnable parameters, which endows the model with strong zero-shot ability, thus mitigating the error accumulation problem [49] in PLL. However, as experimentally suggested, candidate labels will degrade the model's performance as the level of label ambiguity increases, leading to intolerably poor generalization performance. In previous research, it is reasonable for a PLL method to fail to learn from such highly ambiguous candidate labels (an instance with dozens of labels). However, we believe that the powerful pre-trained VLMs are capable of learning from such ambiguous labels in the procedure of fine-tuning.

Accordingly, for the purpose of leveraging the powerful zero-shot ability of VLMs more properly to guide learning with candidate labels, we propose a simple yet effective framework that dynamically mixes the class posteriors predicted by both the handcrafted and learnable prompt, followed by aligning the mixed class posterior with the model output. Besides, because of the simplicity and flexibility of our framework, it can cooperate with any current PLL training objectives. With our framework, the overall performance of PLL methods has improved by a large margin when fine-tuning VLMs with candidate labels.

Our main contributions can be summarized as follows:

- We provide the first study on the scenario when large vision-language models are fine-tuned with only candidate labels.
- We demonstrate empirically and explain that prompt learning is more advantageous than other fine-tuning methods, for learning with candidate labels.
- We propose a framework that guides the process of candidate label disambiguation by aligning the dynamically mixed predicted class posterior of both the handcrafted prompt and the learnable prompt with the model output.
- Extensive experiments demonstrate the effectiveness of our framework.

2 Related Work

Vision-language models with fine-tuning. Recently, significant advancements have been made in the field of vision-language models (VLMs) [19,38,51,52]. Unlike models learning from uni-modal supervision, VLMs align visual and textual signals to learn rich representation from massive image-text pairs in the pre-training stage. One of the keys to the excellent performance of VLMs is the tremendous amount of training data. CLIP [38] trains both the text and image encoder simultaneously using a contrastive loss on a dataset of 400 million image-text pairs. ALIGN [19] leverages a noisy pre-training dataset of 1.8 billion pairs to train the model. However, although VLMs have shown promising performance in generalizing to new concepts without auxiliary information, their large amount of parameters makes it impractical to fine-tune the entire model [25]. Besides, full-parameter fine-tuning will also make large models prone to overfitting to downstream tasks and *catastrophic forgetting* [32]. To address the above issues, multiple transfer learning methods [57,12,38,55] are proposed to adapt VLMs to downstream tasks effectively and efficiently. Linear probe [38] freezes the pre-trained VLM and trains a linear classifier on top of the image encoder. CLIP-adapter [12] introduces an adapter with residual-style feature blending with the pre-trained features. Notably, the success of most of the fine-tuning methods heavily depends on the acquisition of precisely labelled data.

Prompt learning. Among all fine-tuning methods that adapt VLMs to a new task, one typical approach is prompt learning. It treats the text prompt, *e.g.*, "a photo of a $\langle CLS \rangle$ " as continuous learnable parameters, and optimizes the prompt with multiple vision tasks, including image classification [57,56,22,50,20], dense prediction [39,13,26], *etc.* CoOp [57] is the first work that migrated prompt learning to vision tasks, which fine-tunes CLIP by optimizing the parameters of the learnable textual prompt (also called soft prompt) while keeping the class token fixed. MaPLe [22] adds multi-modal prompts and learns them mutually to align both representation spaces dynamically. Moreover, recent studies have revealed the advantages of prompt learning when fine-tuning with weakly supervised or unsupervised data [46,33,17,16]. Wu *et al.* [46] demonstrates that the process of prompt learning is robust to label noise. UPL [17] utilizes handcrafted prompts to generate pseudo labels on unlabelled data and adopts the confident examples per class to tune the learnable prompt.

Partial-label learning. Partial-label learning (PLL) allows each training example to be annotated with a candidate set, containing the true label. Two mainstream strategies have been developed to address this problem: the averagedbased strategy and the *identification-based* strategy. Average-based strategy disambiguates the candidate labels by treating them equally [18,4,54]. Identificationbased strategy regards the true label as a latent variable and selects the most likely label for training [21,9,34,10], which is prone to error accumulation if the wrong label is selected initially [49]. As deep learning thrives, many PLL algorithms have been proposed for training with deep neural network [11,30,29,53]. Feng et al. [11] assumes the generation process of partial labels and derives classifier-consistent and risk-consistent methods from a theoretical perspective. PRODEN [30] updates the model parameters and identifies the true labels seamlessly. PiCO [44] divides the learning process into representation learning by contrastive loss and label disambiguation by prototype and pseudo target updating. In particular, as the scale of the parameters and training data of modern deep neural expands [6.2,23], the deep learning community has embraced a new training paradigm of pre-training and fine-tuning. Nonetheless, to the best of our knowledge, little research has explored PLL under this new training paradigm.

3 Preliminaries of Prompt Learning

In this work, we show that prompt learning is a preferred choice when tuning VLMs with candidate labels and propose a novel framework to augment its performance. Primarily, we conduct the experiments and build our approach upon a prevailing method in prompt learning: **CoOp** [57], which tunes the textual prompt based on a well-known VLM called **CLIP** [38]. In this section, we briefly revisit the details of CLIP and CoOp.

CLIP. CLIP (Contrastive Language-Image Pre-training) is a cutting-edge VLM that learns joint image-text representations through contrastive learning. It consists of both an image encoder and a text encoder. The image encoder encodes visual signals, which can be constructed by ResNet [15] or ViT [7]. The text

encoder encodes textual signals, which is constructed by Transformer [43]. By projecting data from both modalities into a shared representation space, CLIP aligns them with a contrastive loss function. The contrastive loss encourages pairs of image-text embeddings to be pushed closer, effectively learning a powerful multi-modal understanding mechanism. With this pre-training approach, CLIP achieves remarkable performance across various visual tasks, particularly zero-shot image classification. In the zero-shot image classification setting, an image \boldsymbol{x} is encoded into a normalized feature \boldsymbol{f}^v . Likewise, on the text encoder side, a handcrafted prompt of the form "a photo of a <CLS>." is concatenated with the prior class tokens to generate the textual input. After being encoded by the text encoder, assuming the total number of classes is C, a group of normalized text embeddings $\{\boldsymbol{f}_j^t\}_{j=1}^C$ is obtained. Finally, the class posterior is estimated as:

$$p_{\rm zs}(y=i|\boldsymbol{x}) = \frac{\exp(\sin(\boldsymbol{f}^v, \boldsymbol{f}^t_i)/\tau)}{\sum_{j=1}^C \exp(\sin(\boldsymbol{f}^v, \boldsymbol{f}^t_j)/\tau))},\tag{1}$$

where $sim(\cdot, \cdot)$ denotes the cosine similarity, and τ is a temperature factor that controls the range of the output logits.

CoOp. Although CLIP is amazing at zero-shot transfer, its performance is sensitive to differently designed prompts. In order to overcome the inefficiency of the handcrafted prompt designs, CoOp (Context Optimization) [57] replaces the fixed sentence: "a photo of a $\langle \text{CLS} \rangle$." with learnable vectors that have the same dimension as the word embedding of CLIP. These learnable vectors will be optimized with a few labelled examples. In the remaining sections, we will study CoOp as a typical case of prompt learning for VLMs.

To be specific, assume CoOp introduces M learnable vectors $\{\boldsymbol{v}_k\}_{k=1}^M$ and C fixed class tokens $\{\boldsymbol{c}_l\}_{l=1}^C$. Together, they are usually concatenated to form the full prompt $\boldsymbol{s}_i = \{\boldsymbol{v}_1, \boldsymbol{v}_2, ..., \boldsymbol{v}_M, \boldsymbol{c}_i\}$ for class i. Let the normalized image embedding be \boldsymbol{f}^v , then the class posterior is estimated as:

$$p(y = i | \boldsymbol{x}) = \frac{\exp(\operatorname{sim}(\boldsymbol{f}^v, \operatorname{TextProj}(\boldsymbol{s}_i))/\tau)}{\sum_{j=1}^{C} \exp(\operatorname{sim}(\boldsymbol{f}^v, \operatorname{TextProj}(\boldsymbol{s}_j))/\tau)}.$$
(2)

Ultimately, the learnable context vectors $\{\boldsymbol{v}_k\}_{k=1}^M$ are optimized on a dataset $D = \{(\boldsymbol{x}_i, y_i)_{i=1}^N\}$ with the cross-entropy loss:

$$\mathcal{L}_{\text{true}} = -\mathbb{E}_{(\boldsymbol{x}, y) \in D}[\log p(y|\boldsymbol{x})].$$
(3)

Notably, optimizing this training objective of CoOp requires examples of true labels. But in many realistic scenarios, the true label is not accessible due to multiple reasons. Instead, we can obtain a candidate label set Y_i that contains the true label y_i , *i.e.*, $y_i \in Y_i$. Unfortunately, we cannot utilize the candidate label set to optimize the above training objective. Therefore, the next section will study prompt learning with candidate labels.

Fig. 2. Illustration of our framework. Our framework includes a prompt alignment module and a PLL method module. Regarding the prompt alignment module, two different prompts are input to the text encoder, including the handcrafted prompt and the learnable prompt. Afterwards, we mix the recalculated class posteriors yielded by the handcrafted prompt and the soft prompt. Then, the mixed class posterior is aligned with the output of the soft prompt using the re-weighted cross-entropy loss. For the PLL method module, any off-the-shelf PLL training objectives can be combined with the prompt alignment module. It is important to know that during fine-tuning, all the parameters of this framework are **frozen** except for the learnable prompt.

4 Prompt Learning with Candidate Labels

Prompt learning has been shown to be effective when fine-tuning VLMs, provided a few examples with perfect labels. Nevertheless, it remains unclear how prompt learning performs with candidate labels.

In this section, we first empirically demonstrate the superiority of prompt learning with PLL training objectives. Then, we explain why prompt learning performs better with candidate labels. Finally, based on the observations above, we propose a framework that dynamically aligns the mixed class posterior with the model's output to enhance the performance. Figure 2 depicts our framework.

4.1 Pilot Experiments

This part explores prompt learning with PLL training objectives and presents our key findings. The most important observation is that *prompt learning significantly outperforms linear probe with ambiguous supervision*. Linear probe [42,38] is a strong baseline in few-shot learning, which trains a linear classifier on top of the pre-trained frozen image encoder of VLMs. In the following experiments, we will use linear probe and prompt learning to fine-tune the pre-trained model with different types of PLL training objectives to learn from the candidate labels.

Fig. 3. Performance comparison with multiple fine-tuning approaches on UCF101 [40] and Caltech101 [8] with candidate labels of the incremental label ambiguity. Prompt learning and linear probe are incorporated with the PLL training objective of PiCO [44]. vPLL means a simple baseline that treats every candidate label as the ground-truth label and uses cross-entropy loss to learn.

In the pilot experiments, we utilize ResNet-50 [15] as the same visual backbone of the two fine-tuning methods and compare their performance on the datasets of UCF101 and Caltech101 under different levels of label ambiguity. Specifically, We define the level of label ambiguity q as the probability of flipping negative labels $\bar{y}_i \neq y_i$ to false-positive labels inside the candidate label set Y_i : $q = \Pr(\bar{y}_i \in Y_i | \bar{y}_i \neq y_i)$. It is noteworthy that the true label is guaranteed to be inside the candidate label set. For linear probe, the original learning rate is selected from $\{50, 25, 10, 5, 2.5, 1, 0.5, 0.25, 0.1, 0.05, 0.0025, 0.001\}$ to ensure optimal performance. Moreover, the other training settings of linear probe and prompt learning are consistent with the implementation detail in the experiment section. The result is shown in Figure 3.

As seen from Figure 3, although linear probe and prompt learning both achieve excellent performance with true labels, they suffer from performance drop with candidate labels. However, prompt learning is apparently more robust and performs better under all circumstances. In addition, we add a vanilla method for comparison: 'vPLL', which treats every candidate label as the ground-truth label and uses cross-entropy loss to learn from them. Compared with prompt learning + PLL, prompt learning + vPLL performs much worse, showing that the PLL training objective has played a significant part in enabling VLMs to learn effectively from candidate labels.

To summarize, this result shows that prompt learning with PLL training objectives can perform well with candidate labels. However, if the dataset is partialized with a higher level of label ambiguity, the performance of prompt learning will get intolerably worse. (-4.4%) for Caltech101 and -11.3% for UCF101)

The following part will be used to explain why prompt learning is more robust with ambiguous labels than linear probe.

Fig. 4. We record the test accuracy of each epoch of different fine-tuning methods with the PLL training objective: PiCO [44]. Prompt Learning* refers to prompt learning, whose soft prompt is initialized with a handcrafted prompt.

4.2 Reasons for the Robustness of Prompt Learning

In order to investigate the reasons behind the excellent performance of prompt learning, the test accuracy of three models is evaluated by epoch on datasets of UCF101 and Caltech101 when q = 0.3, as shown in Figure 4. The models are:

- Prompt learning with random initialization.
- Prompt learning with a handcrafted initialization (*i.e.*, handcrafted prompt).
- Linear probe

To be clear, the handcrafted prompts of the second variant are chosen from the result of the prompt engineering from CLIP [38].

From Figure 4, we can see that, for prompt learning, the label ambiguity will not sabotage the generalization ability that the VLM initially possesses. Moreover, with a proper PLL training objective, the model can quickly adapt to these training data. Furthermore, even the performance of the model with a randomly initialized prompt can rapidly return to zero-shot performance. Conversely, due to the lack of zero-shot ability, linear probe struggles with the candidate labels at first and cannot learn well from the candidate labels.

In contrast to linear probe, the special position of the tuning parameter of prompt learning keeps the zero-shot ability of VLMs. Even if the tunable prompt is initialized randomly, due to the regularization effect of the fixed class token, the model is more robust to the noisy false-positive labels [46] and will achieve the zero-shot ability to the downstream data through only a few epochs. Remarkably, the zero-shot ability is essential in candidate label disambiguation because it enables the model to select a more likely true label initially, which will mitigate the error accumulation problem [49] in PLL. The error accumulation problem means that since most PLL methods leverage the model's prediction from the previous iteration, the bias will be accumulated and pose a challenge for adjusting mistakes once a false-positive label is identified as the true label, thus severely hurting the generalization of the model. For linear probe, it can only randomly guess which label is correct at first and will significantly suffer from the error accumulation problem. As a result, unlike prompt learning, the pretrained model's powerful representation ability does not effectively contribute to label disambiguation and will later be corrupted by them.

However, we notice that as training proceeds or the label ambiguity increases, the model performance will inevitably be degraded by the candidate labels in prompt learning. Hence, we propose a framework that explicitly utilizes the zero-shot ability of VLMs to learn better from candidate labels.

4.3 The Proposed Framework

Our framework is proposed to further improve the performance of prompt learning with candidate labels. It provides a simple but significant regularization that aligns the mixed prediction of the handcrafted and soft prompt with the current model output using weighted cross-entropy loss. It is shown in Figure 2.

Prompt Alignment Regularization. Let \mathcal{X} be the input space, and $\mathcal{Y} = \{1, 2, \ldots, C\}$ be the label space. The *i*-th learnable prompt $s_i = \{v_1, v_2, \ldots, v_M, c_i\}$, where $\{v_m\}_{m=1}^M$ denotes M learnable tokens and c_i is the the word embedding for the *i*-th class name. Similarly, the *i*-th manually crafted prompt is denoted as h_i . To clarify, $f_i(x; s)$ and $g_i(x; h)$ are the softmax outputs of the *i*-th label, as predicted by the learnable prompt and handcrafted prompt separately. When (x, Y) is drawn from the partialized dataset, the alignment loss is calculated as:

$$\mathcal{L}_{\text{align}}(\boldsymbol{x}, Y) = -\sum_{i=1}^{C} \tilde{p}_i \log f_i(\boldsymbol{x}; \boldsymbol{s}), \qquad (4)$$

where \tilde{p}_i is mixed linearly with the class posteriors predicted by both prompts:

$$\tilde{p}_i = \alpha p(y = i \mid \boldsymbol{x}; \boldsymbol{s}) + (1 - \alpha)p(y = i \mid \boldsymbol{x}; \boldsymbol{h}).$$
(5)

Since the non-candidate labels can never be the ground-truth label, the class posteriors are recalculated as:

$$p(y = i \mid \boldsymbol{x}; \boldsymbol{s}) = \begin{cases} \frac{f_i(\boldsymbol{x}; \boldsymbol{s})}{\sum_{j \in Y} f_j(\boldsymbol{x}; \boldsymbol{s})}, & i \in Y, \\ 0, & i \notin Y. \end{cases}$$
(6)

$$p(y = i \mid \boldsymbol{x}; \boldsymbol{h}) = \begin{cases} \frac{g_i(\boldsymbol{x}; \boldsymbol{h})}{\sum_{j \in Y} g_j(\boldsymbol{x}; \boldsymbol{h})}, & i \in Y, \\ 0, & i \notin Y. \end{cases}$$
(7)

This regularization term can be adapted to any PLL training objective as:

$$\mathcal{L}_{\text{total}}(\boldsymbol{x}, Y) = \mathcal{L}_{\text{PLL}}(\boldsymbol{x}, Y) + \beta \mathcal{L}_{\text{align}}(\boldsymbol{x}, Y).$$
(8)

Dynamic Mixing Strategy. In Equation (5), we use a balancing factor α to mix the handcrafted and soft prompt predictions. However, a fixed balancing factor may be sub-optimal since the performance of the soft prompt will surpass the handcrafted prompt as training goes on. With a fixed α , the performance of the model will be affected by the low-quality predictions of the handcrafted

prompt in the late stages of training. Therefore, a dynamic mixing strategy is adopted to adjust the balancing factor dynamically as:

$$\tilde{p}_i = \alpha(t)p(y = i \mid \boldsymbol{x}; \boldsymbol{s}) + (1 - \alpha(t))p(y = i \mid \boldsymbol{x}; \boldsymbol{h}).$$
(9)

Inspired by PLLCR [47], we define $\alpha(t)$ as:

$$\alpha(t) = \min\{\frac{t}{T'}\lambda,\lambda\}.$$
(10)

The model can prioritize learning from the handcrafted prompt at the beginning of training and then focus on the soft prompt subsequently.

5 Experiments

5.1 Experimental Setting

Datasets. We adopt 10 image recognition datasets: ImageNet [5] and Caltech101 [8] for generic object classification; OxfordPets [36], StanfordCars [24], Flowers102 [35], FGVCAircraft [31], and Food101 [1] for fine-grained classification; SUN397 [48] for scene recognition; UCF101 [40] for action classification; DTD [3] for texture classification. In order to evaluate the model's performance for partial-label learning, as the same in Section 4.1, we define the level of label ambiguity q as the uniform probability of flipping negative labels $\bar{y}_i \neq y_i$ to false-positive labels inside the candidate label set $Y_i: q = \Pr(\bar{y}_i \in Y_i | \bar{y}_i \neq y_i)$. In addition, we use a 16-shot fine-tuning strategy, randomly choosing 16 images per class from the partialized dataset.

Implementation Details. Our implementation is based on Pytorch [37]. We apply prompt learning on a pre-trained CLIP whose backbone of the image encoder is ResNet-50 [15]. The total number of the learnable prompt tokens is 16, and the fixed class tokens are at the end of the prompt. Models are trained with a batch size of 32 and 50 total epochs for each method and dataset, except for ImageNet, which sets the batch size to 256. The optimizer is SGD with a cosine decay schedule annealing the learning rate to 0.00001. The learning rate for prompt learning and our framework is initialized to be 0.002. Following CoOp[57], the learnable vectors are initialized from a zero-mean Gaussian distribution with a standard deviation equal to 0.02. As for the handcrafted prompts of our framework, we follow the result of prompt engineering of CLIP [38]. For the hyperparameters of our method, we set $\lambda = 0.5$, T' = 25, $\beta = 1$. Moreover, if a confidence matrix is required in the PLL method, it will be initialized with the model output before training. We conduct all experiments on eight NVIDIA RTX 3090 GPUs and report the average test accuracy and the standard deviation of 4 experiments while keeping the seeds fixed.

5.2 Main Results

PLL Training Objectives. We prove the effectiveness of our framework by incorporating our framework with six state-of-the-art PLL methods on ten

datasets. PRODEN [30] progressively identifies the true label and updates the model parameters in a seamless manner. CC [11] assumes that the generation process of candidate labels is uniform and is classifier-consistent. LW [45] weights the loss function by considering the trade-off between losses on candidate labels and the non-candidate labels. PiCO [44] divides the learning process into two components: representation learning by contrastive loss and label disambiguation by prototype and pseudo target updating. PLLCR [47] revisits the idea of consistency regularization and performs supervised learning on non-candidate labels and consistency regularization on candidate labels. CAVL [53] utilizes class activation value (CAV) learning that selects the true label with the maximum CAV. The detailed hyperparameter settings and configurations of the above methods are provided in the supplementary material.

Results on Ten Benchmark Datasets. In Table 1, we compare our framework with prompt learning using six PLL methods when $q = \{0.1, 0.3, 0.5\}$. The results of ImageNet and SUN397 are presented in the supplemental material. Our framework has shown consistent improvement over most ambiguous conditions, especially when q = 0.5. For example, in DTD, with PRODEN, our method has gained 1.10%, 1.70% and 10.52%, respectively. Furthermore, in some cases, our framework achieves comparable accuracy with supervised learning, while prompt learning sometimes under-performs zero-shot inference when ambiguity is high. For instance, in OxfordPets with LW at q = 0.5, prompt learning under-performs zero-shot inference by 5.84%, while our method outperforms supervised learning by 2.21%. In addition, in some datasets, the test accuracy of our framework will increase with more label ambiguity, like in Food101 and OxfordPets. We believe these two fine-grained datasets contain considerable label noise [1.36]. which is supported by the result in CoOp [57], so more label ambiguity actually makes the true label more likely in the candidate label set. Since our framework is more capable of dealing with highly ambiguous candidate labels, more ambiguous candidate labels have exerted a relatively more positive effect on our framework. Notably, there are a few cases where prompt learning with CC and PLLCR has outperformed our method. We conjecture that because these two PLL objectives are considered average-based, whose prediction is not based on the prediction from the last epoch, they suffer less from the error accumulation problem and will not benefit from our framework as effectively as other training objectives.

5.3 Further Analysis

In this part, we conduct extensive experiments to assess the effectiveness and stability of our framework by comparing test accuracy with the PLL training objective of PiCO in 3 representative datasets: DTD, FGVCAircraft and Caltech101.

Influence of Different Handcrafted Prompts. Because our framework incorporates handcrafted prompts, it is crucial to determine the performance of our framework with differently crafted prompts. In Table 2, we design some prompts with zero-shot performance lower than the default handcrafted prompts [38] and evaluate our framework with these prompts at different levels of label

Table 1. Performance comparison of prompt learning and our framework. We evaluate the test accuracy of these two methods with different PLL training objectives at different levels of label ambiguity. Supervised means prompt learning with true labels.

ambiguity. Our framework performs better with better-handcrafted prompts. Better handcrafted prompts have resulted in better test accuracy in our experiments, which indicates that the handcrafted prompts indeed guide the fine-tuning process with candidate labels. Our framework is insensitive to differently crafted prompts. Although the performance of our framework is related to different designs of handcrafted prompts, it is not necessary to design the handcrafted prompt intentionally, as the performance of our framework is insensitive to different handcrafted prompts. Our framework outperforms prompt learning by a large margin even when we simply set the handcrafted prompt "<CLS>.".

Dataset	Handcrafted Prompt		CLIP-

Influence of Different Learnable Context Lengths. We evaluate our framework when q = 0.3 while varying the learnable context length of the soft prompt from 1 to 16. The result is shown in Table 3. Our framework is superior with different learnable context lengths. It enhances the performance by a large margin with any of the selected context lengths. The longer, the better. Both methods perform worst when the learnable context length is 1 and improve with a longer length. We conjecture that it is because the neural network with fewer parameters is better calibrated [14], reducing the contribution of the model's zero-shot ability to help disambiguate the candidate labels.

Influence of Different Visual Backbones. We test the effectiveness of our framework with both ResNet-101 and ViT-B/32 across different label ambiguities. The result is shown in Table 4. *Our framework outperforms prompt learning*

with different visual encoders. Both methods perform better with a better backbone. But our framework is more desirable across different backbones.

Effectiveness of the Dynamic Mixing Strategy. To evaluate the efficacy of our dynamic and mixing strategy, ablation studies are conducted on the dynamic and mixing strategies. $\alpha(t)$ is set using the same hyperparameters as the main experiment. The result is shown in Table 5. Both dynamic mixing strategies enhance the model's performance. The model with dynamic technique outperforms all others in 6 and ranked second in 2, out of 9 cases, demonstrating its effectiveness. When only one handcrafted or soft prompt is leveraged, the model's performance declines and cannot surpass the performance achieved when $\alpha = 0.7$. This validates the rationality of the mixing strategy. Lastly, when $\alpha = 1$, it outperforms models with only soft prompt guidance or no guidance in most cases, which, to some extent, justifies the effectiveness of explicitly adopting the handcrafted prompt to guide the learning process.

Robustness to Instance-dependent Candidate Labels. To better simulate the realistic annotation process of candidate labels, we introduce instance-dependent candidate labels and evaluate the performance of our framework under them. Specifically, we use CLIP with the handcrafted prompt of "a photo of a $\langle \text{CLS} \rangle$." to make the zero-shot inference of each example. Then, we select the pseudo labels with top $\{10\%, 30\%, 50\%\}$ confidence as instance-dependent candidate labels. We define the proportion as q, and the result is shown in Table 6. Our framework is more robust with instance-dependent candidate labels. Both prompt learning and our framework have experienced a significant performance drop since the instance-dependent candidate labels are more challenging for the model to disambiguate than uniform candidate labels. However, our framework is more robust and can maintain stable performance with high label ambiguity.

6 Conclusion

This work, for the first time, investigated the scenario when fine-tuning visionlanguage models (VLMs) with candidate labels. Throughout a series of experiments, we empirically demonstrated that prompt learning is superior to other fine-tuning methods when fine-tuning VLMs with candidate labels. However, as the ambiguity of candidate labels increases, the performance of prompt learning is degraded. To alleviate this issue, we proposed a framework that disambiguates candidate labels by aligning the dynamically mixed class posterior of the handcrafted and soft prompt with the model's output to guide the learning process with candidate labels. Comprehensive experimental results on multiple benchmark datasets demonstrate the effectiveness of our proposed framework.
