Abstract

Query rewriting aims to generate a new query that can complement the original query to improve the information retrieval system. Recent studies on query rewriting, such as query2doc, query2expand and querey2cot, rely on the internal knowledge of Large Language Models (LLMs) to generate a relevant passage to add information to the query. Nevertheless, the efficacy of these methodologies may markedly decline in instances where the requisite knowledge is not encapsulated within the model's intrinsic parameters. In this paper, we propose a novel structured query rewriting method called CRAFTING THE PATH tailored for retrieval systems. CRAFTING THE PATH involves a three-step process that crafts query-related information necessary for finding the passages to be searched in each step. Specifically, the CRAFTING THE PATH begins with Query Concept Comprehension, proceeds to Query Type Identification, and finally conducts Expected Answer Extraction. Experimental results show that our method outperforms previous rewriting methods, especially in less familiar domains for LLMs. We demonstrate that our method is less dependent on the internal parameter knowledge of the model and generates queries with fewer factual inaccuracies. Furthermore, we observe that CRAFTING THE PATH demonstrates superior performance in the retrieval-augmented generation scenarios.

1 Introduction

In an open-domain QA system (Lewis et al., 2020b; Zhu et al., 2021; Li et al., 2022; Zhang et al., 2023; Kamalloo et al., 2023), document retrievers are utilized to retrieve the necessary information to answer the given query. Query rewriting reformulates original queries to help the retrieval system find relevant passages. Recent works on query rewriting focus on Large Language Models (LLMs) (Brown et al., 2020; OpenAI, 2022, 2023; Touvron et al., 2023) to generate additional information. Specifically, these studies aim to generate a relevant passage for a given query by leveraging the pretrained knowledge of LLMs. Utilizing these new queries generated from LLMs has shown a significant increase in the performance of retrieval systems. Recently, various LLM based rewriting methods such as query2doc (Q2D) (Wang et al., 2023c), query2expand (Q2E), and querey2cot (Q2C) (Jagerman et al., 2023) have been introduced. Q2D generates a pseudo-document based on the original query, which is then used as input for the retriever. Similarly, Q2C employs a Chain-of-Thought (Wei et al., 2022) approach, and Q2E generates semantically equivalent queries. These approaches leverage the rewriting of the original query into a form similar to passages in the corpus. These techniques result in superior performance improvements compared to the base query alone.

The fundamental reason for utilizing retrieval systems in open-domain QA is to use external knowledge when QA systems do not know to generate correct answer (Gao et al., 2023). And this is the original purpose of using Retrieval-Augmented Generation (RAG) systems (Lewis et al., 2020a; Wang et al., 2023a). However, relying heavily on inherent knowledge of LLMs for query rewriting often leads to the generation of irrelevant information and causes numerous factual errors (Chern et al., 2023; Min et al., 2023; Luo et al., 2023) in the reformulated queries. As in the right examples of Figure 1, Q2C asserts that coffee originated in ancient Egypt or Yemen, whereas its origin is Ethiopia. Meanwhile, Q2D discusses a legendary story about "goats" without providing any information about the origin of the word "coffee". These types of misinformation and unrelated contents can lead to significant performance degradation because of the included incorrect information in the reformulated queries.

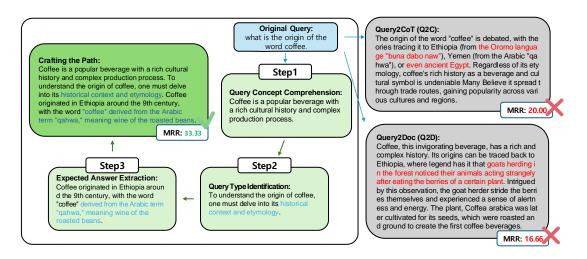

Figure 1: Overview of our proposed query rewriting method CRAFTING THE PATH, along with the rewritten query examples of *query2doc* (Q2D) and *query2cot* (Q2C) methodologies. We represent the factual error in red and the accurate information in blue.

In this paper, we propose a novel query rewriting method, CRAFTING THE PATH, which is a finegrained query reformulation technique through the structured reasoning process. Instead of simply generating the passage similar to the candidate documents, CRAFTING THE PATH focuses on identifying what information needs to be found to solve the given query. The CRAFTING THE PATH method comprises three steps. The first step, Query Concept Comprehension, provides fundamental background knowledge. Offering basic factual information reduces the likelihood of including incorrect information and helps the retrieval system clearly understand the main topic. The second step, Query Type Identification, specifies the required information to filter out irrelevant information. Finally, through Expected Answer Extraction process, the retriever model identifies the essential information it needs to find, facilitating the extraction of accurate passages. This structured, process minimizes unnecessary inferences by the model, thereby reducing the possibility of factual errors.

CRAFTING THE PATH outperforms all of the baseline methods and exhibits a reduced degree of factual errors demonstrated by the 10% higher FActScore (Min et al., 2023) compared to baselines. Additionally, our approach demonstrates enhanced performance without prior knowledge of the model's internal parameters. This is evidenced by experiments in closed-book QA settings, where rewriting models fail to provide correct answers, resulting in a 3.57% increase in retrieval performance. Furthermore, our method shows 7.3% less latency compared to the baselines and also demonstrates superior performance in adopting query rewriting

to open-domain QA scenarios.

2 CRAFTING THE PATH

Our proposed rewriting method, CRAFTING THE PATH, is composed of the following three steps.

2.1 Query Rewriting via CRAFTING THE PATH

2.1.1 Step 1: Query Concept Comprehension

We begin with *Query Concept Comprehension* step, which generates additional information that serves as the contextual background for the existing query. This step enriches the direct information about the question object within the query. This step performs a higher level of abstraction for the original question. As shown in Figure 1, it elaborates on the high-level concept and provides detailed explanations about "coffee," which is part of the original query. *Query Concept Comprehension* step plays a crucial role in generating high-level information while aiding in identifying the information to be searched for in the next step.

2.1.2 Step 2: Query Type Identification

Based on the specific information obtained through the original query and Step 1, we proceed to *Query Type Identification* step. In this step, we generate the necessary information to retrieve relevant passages. Specifically, we create categories for the query that help filter out irrelevant information. To retrieve information to answer the origin of coffee as in Figure 1, we can think that one must search for the historical context and etymology of coffee. This step can filter out irrelevant passages because it specifies the information to be found through rewriting, which serves as input for the retriever model. Inspired by this point, *Query Type Identification* aims to find the type of necessary information that the ground truth passage might include as in Figure 1, and it helps to identify passages containing information on the "historical context and etymology" of coffee.

2.1.3 Step 3: Expected Answer Extraction

The final step involves extracting expected answers for the query based on the information generated from the previous step. As in Figure 1, the details regarding the origin of coffee being Ethiopia and its etymology enable the retriever model to identify the required information, facilitating the extraction of accurate passage.

Input Prompt for CRAFTING THE PATH

Instruction: By following the requirements, write 3 steps related to the Query and answer in the same format as the example.

Requirements:

1. In step1, generate the contextual background from the existing query is extracted.

2. In step2, generate what information is needed to solve the question.

3. In step3, generate expected answer based on query, step1, and step2.

4. If you think there is no more suitable answer, end up with 'None'.

Query 1: what is the number one formula one car? **Step 1:** Formula One (F1) is the highest class of international automobile racing competition held by the FIA. **Step 2:** To know the best car, you have to look at the race records.

Step 3: Red Bull Racing's RB20 is the best car.

(4-shot examples) ...

Query 5:

Table 1: Prompt used for CRAFTING THE PATH.

These three distinct steps offer a form of query rewriting that enhances the retrieval of more accurate information and minimizes the inclusion of incorrect information, resulting in better Opendomain QA performance in Figure 2. We implement all of these steps in CRAFTING THE PATH with a single LLM call using the prompt in Table 1. Specifically, we provide the role of each step with the examples in the prompts. Additionally, to avoid producing inaccurate information, we instruct the model to generate "*None*" when it lacks certain knowledge, providing clear guidance for the retriever system's input.

2.2 Passage Retriever

Constructing Inputs of Retriever To construct the final query q^+ , we expand the original query qthree times and concatenate q with rewritten query QR in sparse retrieval as shown in Eq. 1. In the case of dense retrieval, a [SEP] token is inserted between the query and the QR to differentiate them.

Sparse:
$$q^+ = \operatorname{concat}(\{q\} \times 3, QR).$$
 (1)

Dense:
$$q^+ = \operatorname{concat}(q, [SEP], QR).$$
 (2)

Training Dense Retriever To train a dense retriever, we utilize the Binary Passage Retrieval (BPR) loss (Yamada et al., 2021) as follows to reduce the memory usage:

$$\mathcal{L}_{\text{cand}} = \sum_{j=1}^{n} \max(0, -(\langle \tilde{\mathbf{h}}_{q_{i}}, \tilde{\mathbf{h}}_{p_{i}^{+}} \rangle + \langle \tilde{\mathbf{h}}_{q_{i}}, \tilde{\mathbf{h}}_{p_{i,j}^{-}} \rangle) + \alpha). \quad (3)$$
$$\mathcal{L}_{\text{rerank}} = -\log \frac{\exp(\langle \mathbf{e}_{q_{i}}, \tilde{\mathbf{h}}_{p_{i}^{+}} \rangle)}{\exp(\langle \mathbf{e}_{q_{i}}, \tilde{\mathbf{h}}_{p_{i}^{+}} \rangle) + \sum_{j=1}^{n} \exp(\langle \mathbf{e}_{q_{i}}, \tilde{\mathbf{h}}_{p_{i,j}^{-}} \rangle)} , \qquad (4)$$

where $\mathcal{D} = \{\langle q_i, p_i^+, p_{i,1}^-, \cdots, p_{i,n}^- \rangle\}_{i=1}^m$ denote a set where *m* represents training instances, p_i^+ denotes a positive passage, and $p_{i,j}^-$ denotes a negative passage. We compute embedding $e \in \mathbb{R}^d$ using an encoder, each \tilde{h}_q and \tilde{h}_p represent the hash code for a query and a passage, respectively. \mathcal{L}_{cand} is to identify positive passages based on ranking loss, and α is the margin that is enforced between the positive and negative scores. \mathcal{L}_{rerank} is used to minimize the negative log-likelihood for a positive passage. Finally, we employ the BPR loss as follows:

$$\mathcal{L}_{bpr} = \mathcal{L}_{cand} + \mathcal{L}_{rerank}.$$
 (5)

3 Experiments

3.1 Experimental Setup

Datasets We use the MS-MARCO passage dataset (Campos et al., 2016) for training retriever. Additionally, To demonstrate the robustness of our model on unseen data, we utilize nine retrieval datasets from BEIR (Thakur et al., 2021) for our main experiment. In our experiment, we utilize the nDCG@10 metric to evaluate the quality of the top 10 search results based on their relevance and order. Additionally, we use the HotpotQA (Yang et al., 2018) and NaturalQA (Kwiatkowski et al., 2019) datasets for the open-domain QA experiment and measure the accuracy.

Table 2: Experimental results on BEIR dataset. Highest performance is highlighted in **bold**, and the second highest is underlined.

Baselines To analyze query rewriting methods based on LLMs, we use three baselines: *query2doc* (Q2D), *query2cot* (Q2C), and *query2expand* (Q2E). All rewriting methods use 4-shot prompts. For Q2D, Q2E and Q2C, we reference the prompt from Wang et al. (2023c), and Jagerman et al. (2023). In our experiments, we employ Mistral-7b (Jiang et al., 2023) and Phi-2 (Microsoft, 2023) as query rewriting models including CRAFTING THE PATH. We conduct both dense and sparse retrieval experiments with all rewriting methods on the 9 BEIR datasets.

Implementation Details For reliable experiments, we train five different retriever models using a different seed for each method. To evaluate the query rewriting methods using dense retrieval models, we use a total of 20 models. For each dataset, we construct 5 (*fine-tuned retrieval models*) \times 4 (*rewriting methods*) = 20 embedding vectors, and compute the mean and variance. In experiments with the query rewriting method using Phi-2, we obtain results using models trained with the new queries written by Mistral-7b. We employ all-mpnet-base-v2¹ as our pre-trained dense retrieval model. For the sparse retriever system, We use the default BM25 parameters provided by pyterrier (Macdonald and Tonellotto, 2020)².

3.2 Results

Main Results As shown in Table 2, CRAFT-ING THE PATH outperforms all approaches, including query2doc (Q2D), query2cot (Q2C), and query2expand (Q2E), for the average score across 9 BEIR datasets. Our approach consistently demonstrates superior performance compared to existing methods. CRAFTING THE PATH provides a robust application across various domains and rewriting model sizes in both sparse and dense retrievers. Moreover, we observe significant performance improvements on the trec-covid (Wang et al., 2020; Voorhees et al., 2020) and nfcorpus (Boteva et al., 2016) datasets for both retriever types compared to previous methods. Especially, trec-covid dataset requires searching for the latest information on queries about COVID-19. CRAFTING THE PATH proves to be more effective in finding such recent information. However, previous methods outperform our approach on datasets like FEVER (Thorne et al., 2018). The FEVER dataset is based on Wikipedia, which is frequently used for LLMs pretraining data. Since the training data for the Mistral-7b and Phi-2 models are not disclosed, and verifying the presence of internal parameter knowledge directly remains a challenge, it is difficult to confirm the internal knowledge of the models (Wang et al., 2023a). However, we conduct measurements of the impact of model's internal parameter knowledge through experiments in Table 4. As results in Table 2, we observe the significant performance improvements in these BEIR datasets from CRAFT-

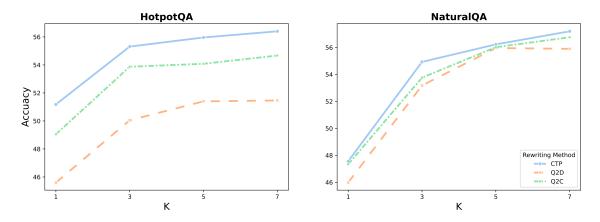

Figure 2: The Retrieval-Augmented Generation performance of HotpotQA (left) and NaturalQA (right), when performing CRAFTING THE PATH (CTP), *query2doc* (Q2D), and *query2cot* (Q2C). K means the number of retrieved passages.

	MS-MARCO Passage dev				
	nDCG	MRR	Recall@1K		
CRAFTING THE PATH	45.42	33.11	97.05		
w/o step3	44.99	32.91	96.67		
w/o step2, 3	44.59	32.42	96.17		

Table 3: Ablation study on CRAFTING THE PATH method.

ING THE PATH rewriting methods through the use of a structured rewriting method.

Ablation Study We conduct an ablation study on the CRAFTING THE PATH method to observe the influence of each step. We measure the performance on the MS-MARCO dataset by excluding each step as shown in Table 3. Also, We utilize nDCG, MRR, and Recall@1K to measure performance. Our experiment with omitting Step 3 and also conduct experiments excluding both Steps 2 and 3. Performance declines with the removal of each step, demonstrating that each step is essential for performance improvement.

3.3 Analysis

Measuring the Reliance on Internal Knowledge To evaluate the reliance of the internal model parameter knowledge in query reformulation of each LLM, we divide the dataset into problems where each LLM can generate the correct answer and those where it cannot in a closed-book setting. Based on this division, we apply three rewriting methods and measure MRR and nDCG@10 scores as shown in Table 4. Both the Mistral-7b and Phi-2 models demonstrate superior performance in the INCORRECT ANSWER cases when using our rewriting method, compared to previ-

HotpotQA	Co	rrect Ans	wer	Inco	orrect Answer	
Mistral-7b	Ours	Q2D	Q2C	Ours	Q2D	Q2C
nDCG@10	77.80	76.00	79.27	60.05	55.57	58.77
MRR	90.04	87.73	90.90	78.76	71.71	75.35
Phi-2	Ours	Q2D	Q2C	Ours	Q2D	Q2C
nDCG@10	74.72	71.03	75.43	59.42	46.93	57.64
MRR	87.95	86.17	87.75	79.16	64.63	75.59

Table 4: The impact of reliance on rewriting modelinternal knowledge.

ous rewriting approaches. This demonstrates that our method achieves more effective information retrieval when the model needs to search unknown information, aligning with the original purpose of using RAG (Lewis et al., 2020a) which is to use external knowledge when QA systems do not have knowledge to generate correct answer. In this experiment, we use the Contriever (Izacard et al., 2022) model for the dense retriever.

Evaluating on Open-Domain QA To evaluate the answer generation results based on retrieved passages, we conducted performance measurements using HotpotQA (Yang et al., 2018) and NaturalQA (Kwiatkowski et al., 2019) datasets. We performed retrieval using rewritten queries, altering the number of passages retrieved with three different rewriting methods to measure accuracy as follows:

$$q' = \mathcal{M}_{\text{rewriting}}(\text{prompt}(q)) \tag{6}$$

$$p_1, \dots, p_k = \mathcal{M}_{\text{Retriever}}(q')$$
 (7)

 $output = \mathcal{M}_{Generator}(prompt(q, p_1, ..., p_k)) \quad (8)$

Both the generation and rewriting models utilized the Mistral-7b (Jiang et al., 2023) model, while

Delete New Queries with Answer			
CRAFTING THE PATH	58.29	77.46	
query2doc (Q2D)	53.39	69.91	
query2cot (Q2C)	56.54	73.68	

Table 5: The results of an answer modification experiment.

the Contriever (Izacard et al., 2022) model served as the retrieval model. In Eq 6 and 7, q is the original query, and q' is the rewritten query, while p_1, \ldots, p_k represents the retrieved passages, and the retriever searches the top k most relevant passages. We generate the final answer based on the retrieved passages and the query as shown in Eq 8. For more details on our prompts refer to the Appendix A.2. Figure 2 illustrates that our rewriting approach yields the best performance across both HotpotQA and NaturalQA. Additionally, we observed that the Q2D method's performance decreases when the number of passages (k) reaches seven. However, the CRAFTING THE PATH method demonstrates superior accuracy compared to the Q2D and Q2C methods. Our method performs better in situations where the rewriting model generates incorrect answers, making it effective for open-domain QA. We conduct an analysis of this in Tables 4 and 5.

Experiment on the Impact of Answer Presence We examine the changes in retrieval performance based on the presence or absence of answers. In Table 5, rewriting the HotpotQA dev dataset (Yang et al., 2018), comprising 5,447 entries using Mistral-7b, results in new queries that include 1,746, 1,623, and 1,752 answers for CRAFT-ING THE PATH, Q2D, and Q2C, respectively. To evaluate the impact of our model's reliance on internal knowledge for generating answers, we conducted three experiments. First, in the New Query setting, we directly utilize the new queries generated by the LLM. Second, in the Replace Answer to [MASK] setting, if the new query contains an answer, we mask the answer portion. Finally, in the Delete New Queries with Answer experiment, we exclude any new queries from the evaluation if at least one of the three rewriting methods generated a new query containing an answer. The evaluation

BEIR	FActScore				
DEIK	Crafting the Path	Q2D	Q2C		
Mistral-7b	0.718	0.506	0.711		
Phi-2	0.765	0.460	0.675		

Table 6: Average FActScore (Min et al., 2023) on each method.

dataset reduces to 3,212 in *Delete New Queries with Answer* experiment. Our approach achieves the best performance across all three experiments. We observe that replacing answers with *[MASK]* results in a decrease in MRR and nDCG@10 performance across all rewriting methods. Notably, the difference in nDCG@10 scores between our method and Q2C was 0.45 in the first experiment and 1.75 in the third experiment. This score gap suggests that our approach is relatively less affected by the presence or absence of answers in the queries compared to existing methods.

Evaluating the Factuality of Queries To determine the impact of factual errors occurring during query rewriting on retrieval performance, we use FActScore to measure the accuracy of Mistral-7b and Phi-2 across three rewriting methods. Unlike Min et al. (2023), which uses atomic facts, we simply divide the content by sentence. For each separated sentence, we use a gold label passage as evidence to output as True or False. If the factuality evaluation results for three sentences of a rewritten query are True, True, False, we assign a score of 2/3. We calculate the average for the measured queries. In Table 6, CRAFTING THE PATH exhibits the highest FActScore (the smallest factual error), demonstrating the best performance with both the Mistral-7b and Phi-2 models. We utilize GPT-3.5 Turbo (OpenAI, 2022, 2023) as the factuality evaluation model.

Query Length and Latency In Figure 3, we compare the query length for each rewriting method. Additionally, we include the prompts utilized for each rewriting method in Appendix A.2. We observe that the CRAFTING THE PATH approach has a shorter context length than all other methods except for Q2E. Our approach maintains a structured format, which allows us to minimize unnecessary word generation while achieving superior performance. In Table 8, since all three methods use the same dense retriever architecture, the search time is equal. Therefore, we measure the search time using the sparse retriever (BM25)

Case	Question	Crafting the Path	query2cot (Q2C)
Case 1: Effectiveness of generating None.	Question: What is an rs in money?	New Query: The abbreviation "RS" does not have a standard meaning in the context of money or fi- nance. To understand the meaning of "RS" in a given financial context, additional context or clarifica- tion from the source is required. None. - (MRR: 33.3)	New Query: In finance, an RS (Relative Strength) ratio is a technical indicator that compares the stock's performance against a benchmark index or another stock. It measures the strength of a secu- rity's price action in relation to the market, helping investors identify potential outperformance or under performance (MRR: 12.5)
Case 2: Errors in a pre- vious step lead to issues in sub- sequent genera- tion.	Question: What is sim- plicheck?	New Query: Simplicheck is a term or concept that may represent a specific tool, process, or concept, but without further context, its meaning remains unclear. To understand what Simplicheck is, more information or context is required. None. - (MRR: 16.7)	New Query: Simplicheck is a software tool designed for automated vulnerability scanning and penetration testing. It helps identify security weaknesses in web applications, networks, and systems, enabling organizations to prioritize and remediate risks effectively (MRR: 100)
Case 3: factual errors occur.	Question: Tricare service number.	New Query: TRICARE is a health program for eligible active duty and retired military person- nel, their families, and survivors. To access TRI- CARE services, members need to provide their unique identifier, such as a service number. he TRI- CARE service number is a 12-digit identifier, typi- cally formatted as NNN-NNN-NNN-NN-NN-NN. - (MRR: 11.11)	New Query: TRICARE is a health program for active-duty military, retirees, and their families. To obtain specific information, contact TRICARE Customer Service at 1-877-874-2273 (option 1) for enrollment, eligibility, and benefits inquiries. This number ensures access to accurate and timely information (MRR: 20)

Table 7: Case study of reformulated queries generated using Mistral-7b with Crafting the Path and Q2C. MRR represents the retrieval performance when using the new query. We represent the factual error in red and the accurate information in blue.

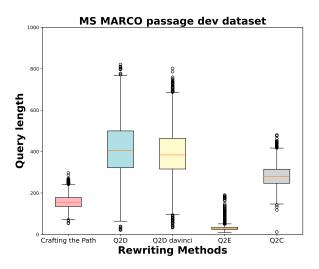

Figure 3: The length of the new query for each rewriting method in the MS-MARCO passage dev dataset.

instead. Hence, we measure the time of LLM call latency to compare the speed of each method. We retrieve results from the MS-MARCO passage dev dataset (Campos et al., 2016) for 1,000 entries and average the outcomes over 100 repetitions. We measure the latency incurred when the model generates a new query and BM25 searches for relevant passages. Our method generates less redundant information, resulting in lower latency compared to Q2D. Also, our method shows comparable latency to Q2C because both methods have a low context length.

Case Study In Table 8, we conduct a representative case analysis of both the strengths and limi-

	LLM call	Index search
CRAFTING THE PATH	5648.9ms	261.44ms
query2doc (Q2D)	8167.5ms	335.65ms
query2cot (Q2C)	6094.2ms	281.98ms

Table 8: Latency analysis of each method in BM25 search and LLM call from the MS-MARCO passage dev dataset.

tations of our proposed method. Case 1 shows an improvement in performance by minimizing factual errors by generating "None". In contrast, we observe factual errors occurring in Q2C during the reasoning process for answer generation. The retrieval performance of Q2C decreases compared to CRAFTING THE PATH due to these factual errors. Conversely, our method generates "None" for unknown contexts, minimizing factual errors and improving retrieval performance. In Case 1, RS is the currency of India. Q2C generates an explanation of the RSI performance indicator. In Case 2, We demonstrate that errors in a previous step propagate in subsequent generations. The CRAFTING THE PATH method fails to provide a correct explanation of Simplicheck in step 1, the Query Concept Comprehension process. In subsequent steps, it indicates that more information is needed. Also, as in Case 3, our method does not completely eliminate factual errors. In the case of Q2C, it generates the correct number, resulting in better retrieval performance. On the other hand, our method generates

the wrong number format. Additionally, the proportion of queries that generated "None" among all rewritten queries is 3.3%.

4 Related Work

Information Retrieval Information retrieval is the process of obtaining relevant information from the database based on given queries. The main two methods for information retrieval are sparse retrieval and dense retrieval. A prominent example of the sparse retrieval method is BM25 (Robertson and Jones, 1976; Robertson et al., 1995), which serves as a ranking function to evaluate the relevance between a given query and documents. In contrast, dense retrieval method (Xiong et al., 2021; Qu et al., 2021) involves fetching passages that exhibit high similarity to the query using the document embeddings. This approach typically utilizes pre-trained language models such as BERT (Devlin et al., 2018) for the encoder, and some methods fine-tune these encoders. (Karpukhin et al., 2020; Wang et al., 2023b). In this work, we improve the performance of both sparse and dense retrieval methods by focusing on query rewriting method.

LLM Based Query Rewriting Query rewriting refers to the task that modifies the original query to improve the search results for the information retrieval systems. Some studies on query rewriting have employed neural networks to produce or select expansion terms (Zheng et al., 2021; Roy et al., 2016; Imani et al., 2019), typically through training or fine-tuning a model. In contrast, our approach leverages the inherent capabilities of Large Language Models (LLMs) without requiring training or fine-tuning. Recent studies on query rewriting mainly use the large language models to create relevant information for the given query. query2doc (Q2D) (Wang et al., 2023c) operates by generating a pseudo-document based on the original query, which is then used as input for retriever. Similarly, query2cot (Q2C) employs a Chain of Thought (CoT) (Wei et al., 2022) approach, and query2expand (Q2E) (Jagerman et al., 2023) generates semantically equivalent query. These approaches leverage the rewriting of the original query into a form similar to passages in the corpus. This technique leads to significant performance improvement compared to using the base query alone. Furthermore, Rewrite-Retrieve-Read(Ma et al., 2023) introduces a methodology that enhances rewriting performance by incorporating reinforcement learning. Another study, *ITER-REGEN*(Shao et al., 2023), improves query quality by feeding the query and retrieved documents into a language model for rewriting, followed by a repeated retrieval process. *Rephrase and Respond* (Deng et al., 2023) argues that for effective rewriting, queries should be rephrased in a manner that is easier for LLMs to understand. For the conversational serach, (Yoon et al., 2024) proposes a method that generates a variety of queries and uses the rank of retrieved passages to train the LLMs on only the optimal queries. This process is further refined using a DPO (Rafailov et al., 2023) approach to create optimal queries.

Our work has similarities with recent efforts like Q2D (Wang et al., 2023c) and Q2E (Jagerman et al., 2023), particularly in using linguistic techniques to expand queries. Q2D and Q2C perform well on queries where the rewriting model can produce accurate answers, but their performance significantly deteriorates when inaccurate answers occur. However, unlike previous approaches, we focus on rewriting queries to improve search performance when the model generates incorrect answers. We demonstrate significant improvements in QA tasks through this problem mitigation. Additionally, we aim to minimize the generation of inaccurate information and concentrate on producing the necessary data for information retrieval.

5 Conclusion

We present a Crafting the Path, an approach that involves a structured three-step process, focusing not merely on generating additional information for the query but primarily on generating what information to find from the query. Our approach shows superior retrieval performance compared to the existing rewriting method, achieves improved performance in open domain QA by being less reliant on internal model knowledge and demonstrates robust performance across various models. Additionally, the method generates fewer factual errors and delivers improved out-of-domain performance with lower latency than previous methods.

Tasks such as query rewriting in information retrieval can benefit from the advancements in LLMs. Additionally, as LLMs become more universally accessible, they can become a central part of information retrieval systems. This offers the advantage of providing users with more accurate information.

Limitations

Our method outperforms existing ones, but using an LLM for query rewriting inherently introduces latency. However, we propose a rewriting method that, compared to existing methods, results in relatively lower latency while offering better retrieval performance. Additionally, we experimentally demonstrate scenarios where rewriting can and cannot generate answers. However, we do not present an automatic method to distinguish between these scenarios in actual applications. We leave the study of such methods for future research.

Ethics Statement

This study conducts query rewriting and QA tasks using an LLM, and also searches for relevant documents. Since we carry out generation tasks based on the LLM, it is important to be aware that the LLM may produce inappropriate responses. Additionally, as it may retrieve inappropriate content from the searched documents, developing management methods for this is essential. We believe this is a crucial area for future work.

A Appendix

A.1 Hyperparameters

We present the detailed hyperparameters in Table 9.

Name	Value
Learning rate	2e-5
PLM	all-mpnet-base-v2
Batch	128
Epoch	3
Learning rate decay	linear
Warmup steps	1000
Binary loss margin	2.0
Similarity function	dot score
Query length	128
Passage length	128

 Table 9: Hyperparameters used to train dense retrieval model.

A.2 Prompts

Instruction: Based on the example below, write 3 steps related to the Query and answer in the same format as the example.

Requirements:

1. In step1, sub-information from the existing query is extracted.

- 2. In step2, please generate what information is needed to solve the question.
- 3. In step3, an answer is generated based on Query, step1, and step2.
- 4. If you don't have certain information, generate 'None'.
- 5. Please prioritize your most confident predictions.

Example:

Query: where is the Danube?

step1: The Danube is Europe's second-longest river, flowing through Central and Eastern Europe, from Germany to the Black Sea.

step2: To locate the Danube precisely, geographical knowledge or a map of Europe highlighting rivers is necessary.

step3: The Danube flows through 10 countries.

Query: what is the number one formula one car?

prompts **step1:** Formula One (F1) is the highest class of international automobile racing competition held by the FIA.

step2: To know the best car, you have to look at the race records. **step3:** Red Bull Racing's RB20 is the best car.

Query: which movie did Michael Winder write?

step1: Michael Winder is a screenwriter involved in the film industry, potentially credited with writing one or more movies.

step2: To identify the movie(s) Michael Winder wrote, access to a film database or filmography reference is needed.

step3: Michael Winder wrote the movie "In Time" (2011).

Query: who's the director of Predators?

step1: "Predators" is a film, and like all films, it has a director responsible for overseeing the creative aspects of the production.

step2: To identify the director of "Predators," one needs access to movie databases, film credits, or industry knowledge about this specific film.

step3: Nimród Antal is the director of "Predators" (2010).

Query:

Table 10: The full prompt used for CRAFTING THE PATH method.

Instruction:

You are good at writing Passage. You are asked to write a passage that answers the given query. Do not ask the user for further clarification.

Requirements:

1. Please write it in a similar format to the example

2. Please prioritize your most confident predictions.

Example:

Query: what state is this zip code 85282

Passage: Welcome to TEMPE, AZ 85282. 85282 is a rural zip code in Tempe, Arizona. The population is primarily white, and mostly single. At \$200,200 the average home value here is a bit higher than average for the Phoenix-Mesa-Scottsdale metro area, so this probably isn't the place to look for housing bargains.5282 Zip code is located in the Mountain time zone at 33 degrees latitude (Fun Fact: this is the same latitude as Damascus, Syria!) and -112 degrees longitude.

Query: why is gibbs model of reflection good

Passage: In this reflection, I am going to use Gibbs (1988) Reflective Cycle. This model is a recognised framework for my reflection. Gibbs (1988) consists of six stages to complete one cycle which is able

prompts

to improve my nursing practice continuously and learning from the experience for better practice in the future.n conclusion of my reflective assignment, I mention the model that I chose, Gibbs (1988) Reflective Cycle as my framework of my reflective. I state the reasons why I am choosing the model as well as some discussion on the important of doing reflection in nursing practice.

Query: what does a thousand pardons means

Passage: Oh, that's all right, that's all right, give us a rest; never mind about the direction, hang the direction - I beg pardon, I beg a thousand pardons, I am not well to-day; pay no attention when I soliloquize,

it is an old habit, an old, bad habit, and hard to get rid of when one's digestion is all disordered with eating food that was raised forever and ever before he was born; good land! a man can't keep his functions regular on spring chickens thirteen hundred years old.

Query: what is a macro warning

Passage: Macro virus warning appears when no macros exist in the file in Word. When you open a Microsoft Word 2002 document or template, you may receive the following macro virus warning, even though the document or template does not contain macros: C:\<path>\file name>contains macros. Macros may contain viruses.

Query:

Table 11: The full prompt used for query2doc (Q2D) method.

Instruction:

Based on the example below, write keywords. Do not ask the user for further clarification

Requirements:

Please write it in a similar format to the example
 Please prioritize your most confident predictions.

Example:

Query: how to include bullets in excel **Keywords:** insert bullet points in excel

prompts

Query: positive predictive value formula **Keywords:** calculating positive predictive value
